Bald Eagles consume fish, mammals, and birds (Stalmaster 1987. The Bald Eagle. Universe Books, New York. pp. 92-95; Gerrard and Bortolotti 1988. The Bald Eagle: Haunts and Habits of a Wilderness Monarch. Smithsonian, Washington, D.C., p. 29; Todd et al. 1982. J. Wildl. Manage. 46:636-645). Reptiles are not a frequent food item (Clark 1982. J. Field Ornithol. 53:49-51; Stalmaster op. cit., pp. 95-96). Various invertebrates have also been reported but amphibians are uncommonly taken. McEwan and Hirth (1980. Condor 82:229-231) found trace quantities (n = 4) of the greater siren (*Siren intermedia*) in 16 eagle nests they examined in Florida.

To my knowledge, this constitutes the only direct evidence of frogs as a Bald Eagle food item. Amphibians, in general, are probably underrepresented in eagle food habits samples because no hard structures such as bones or hair remain after feeding as when birds or mammals are consumed.

CAUDATA

HYDROMANTES PLATYCEPHALUS (Mount Lyell Salamander). **Toxicity.** Noxious or toxic skin secretions are widespread among salamanders, including plethodontids (Brodie 1977. Copeia 1977(3):523-535). This note reports a toxic reaction, including temporary blindness, in a human in response to the skin secretions of an adult Mount Lyell Salamander (*Hydromantes platycephalus*). The case history that follows was obtained by personal interview 21 November 1985 with the subject, Mr. Dale Mitchell. Mr. Mitchell is a biologist with the Region 4 Office of the California Department of Fish and Game in Fresno. He is well acquainted with *H. platycephalus*, having searched for it numerous times previously on backpacking trips in the Sierra Nevada. Several new locality records are the result of his field work.

During August 1984, Mr. Mitchell, in the company of his wife (a physician) undertook a backpacking trip in the high Sierra Nevada. The locality of the incident described below is as follows: Calif., Fresno Co., ca. 0.2 km below (S of) Bighorn Lake, along outflow creek (trib. to North Fork Mono Creek), T.5S., R.28E., Sec. 35, elev. ca. 3290 m (SE of Mt. Izaak Walton).

On the afternoon of the second day of their trip, they observed an adult *H. platycephalus* crawling from under a rock that Mr. Mitchell's wife had sat on. The salamander did not appear to be injured. During the next 10 min, the salamander was handled extensively by Mr. Mitchell in an effort to photograph it. The salamander exhibited various defensive behaviors (e.g., arched back, elevated tail, and immobility). During this time, Mr. Mitchell inadvertently rubbed his eyes with his fingers and experienced an immediate reaction—a burning sensation and tearing, whereupon he rubbed his eyes again (not having realized the source of the irritation). The burning sensation became more pronounced and he experienced considerable pain. At this point, he and his wife decided to quickly hike up the slope to the lake where he could rinse his eyes thoroughly. By the time they reached the lake edge (ca. 5 min later), his vision had deteriorated to the extent that he had difficulty distinguishing objects in his path. At the lake, he submerged his head in the water and rinsed his eyes thoroughly, and washed his hands. A short while later, his visual field had become all white; he described it as "milky." He was completely blind, unable to distinguish between light and dark.

The burning sensation continued for 10-12 h post-contact. Eyes were rinsed with water every 2 h. His eyes appeared bloodshot (according to his wife). He took aspirin to relieve the pain. He experienced considerable anxiety throughout the course of this incident. He slept little during the night, and by the next morning his vision had not returned, though the burning had subsided. Loss of vision continued through the day, but gradual recovery was evident late that evening (ca. 30 h post-contact).

By the following morning, he had partial vision. He experienced an aching in the eye musculature, particularly when the eyes were moved. Aspirin was again taken to relieve pain. A soreness in the orbits continued for ca. 14 days.

Mr. Mitchell estimates that complete visual recovery was realized ca. 4.5 days (108 h) post-contact. No medical treatment was sought due to the difficulty of leaving their remote location in the back country.

TESTUDINES

APALONE SPINIFERA EMORYI (Texas Spiny Softshell). **Defensive Behavior.** Defensive posturing has been described in seven families of turtles (Hayes 1989. Herp. Review 20(1):4-5), but apparently has not been reported in the softshells (Trionychidae). We report on defensive behavior exhibited by adult specimens of *Apalone spinifera emoryi* collected in the Rio Grande and the Pecos River of New Mexico during 1989-90. Seven specimens (184-391 mm CL) taken in Sandoval Co. (3 females), Valencia Co. (1 male, 1 female), and Guadalupe Co. (1 male, 1 female) were tested for defensive responses within one to six days following capture. Testing methodology and descriptive terminology used follow Hayes (op. cit.).

Frontal stance. The two largest females (391 and 399 mm CL) responded to frontal tapping of the carapace by drawing in the head and forelimbs and by completely extending the hindlimbs. The tail was also extended and elevated firmly against the ventral surface of the rear margin of the carapace. Although similar to the stance reported for *Chelydra serpentina* (Dodd and Brodie 1975. Herpetologica 31(3):286-288), the plastron was not elevated above the substrate to the same degree, the forelimbs were not extended, and the tail was not used as a support. The posterior end of the plastron was elevated by ca. 2 cm. Duration of the behavior appeared to be dependent upon the stimulus; the posture was quickly abandoned when tapping was stopped.

Lateral stance. The same turtles that exhibited the frontal stance also displayed the lateral response which involved the extension of the hindlimb opposite the stimulus, but not the extension of the corresponding forelimb. The result was a somewhat oblique orientation of the carapace toward the perceived threat. Plastron elevation and display duration were as above.

Other responses. The primary de-

fensive response in all specimens was withdrawal of the head and limbs, and frontal stimuli (both tactile and visual) generally elicited a biting response (in more aggressive specimens) or further withdrawal of the head. Tapping the lateral or rear margins of the carapace generally resulted in no response or movement away from the stimulus in the non-posturing turtles. In at least three specimens, the posterior margin of the carapace was bent downward when tapped. The rear stance described by Hayes (op. cit.) was not elicited in any of the seven specimens. The most passive response (complete withdrawal of head and limbs; no attempt to escape or bite) was by a male (184 mm CL).

Hayes et al. (1988. Herpetologica 44(1):11-17) noted that intensity of defensive displays in some turtles are less distinctive and aggressive than the postures reported for *C. serpentina*, probably due to differences in morphology, shell protection, and ecology. *Apalone* are physically incapable of elevating the body above the substrate to the same degree as *Chelydra*, and the carapace and plastron in softshells afford relatively little protection against a predator. Escape and aggressive behavior that allows escape (e.g., biting) are therefore probably most important to these turtles when threatened. Also, the selective pressure for the development of stereotyped defensive displays on land may be limited in softshells by their highly aquatic habits. Our preliminary data suggest that defensive display behavior is used infrequently by *A. s. emoryi* and may be most common in large female specimens, possibly as an adaptation for extended activity away from water during egg-laying.

Specimens retained during this study will be deposited in the Museum of Southwestern Biology, University of New Mexico. We thank Norman J. Scott, Jr. for comments on the manuscript.

Submitted by **JAMES N. STUART** and **CRAIG S. CLARK**, Environmental Section, U.S. Army Corps of Engineers, Albuquerque, NM 87103-1580 (JNS, CSC) and Department of Biology, University of New Mexico, Albuquerque, NM 87131, USA (CSC, JNS) ●

CHELYDRA SERPENTINA (Common Snapping Turtle). **Fecundity.** We report here on the contents of a nest that we discovered 12 June 1990 on the Valentine National Wildlife Refuge, Cherry Co., Nebraska. The nest contained a clutch of 109 eggs. This value eclipses the previous record of 104 eggs produced by another female from the same population (Miller et al. 1989. Herp. Review 20:69). A subsample of 40 eggs that were weighed prior to being used in another study has an $\bar{X}$ mass of 12.42 g (range 9.95-13.25 g), which leads to an estimate of 1.354 kg for the mass of the entire clutch. This is an impressive value for parental investment by a snapping turtle, but still falls short of the estimate of 1.444 kg for the clutch reported earlier (Miller et al., op. cit.).

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **Migration.** Leatherback turtles are the most widely distributed of all reptiles, ranging throughout tropical and temperate oceans of the world, into boreal waters. Individual records of long distance leatherback movements in the western north Atlantic currently consist of females tagged while nesting in the tropics, and subsequently recaptured or stranded in temperate latitudes (Boulon et al. 1988. Herp. Review 19(4):88; Lambie 1983. Marine Turtle Newsletter 24:17); Pritchard 1976. Copeia 1976(4):749-754). While these data support the belief that leatherbacks travel between tropical nesting grounds and northern feeding areas (Bleakney 1965. Can. Field Nat. 79(2):120-128; Lazell 1980. Copeia 1980(2):290-295; Rhodin and Schoelkopf 1982. Copeia 1982(1):181-183), there are no records of leatherbacks from northern waters subsequently found in their southerly nesting areas.

Many leatherbacks are observed on routine aerial surveys off the mouth of Chesapeake Bay, presumably feeding on the abundant jellyfish washing out of the Bay (Keinath et al. 1987. Virginia J. Sci. 38(4):329-336; Musick 1988. The Sea Turtles of Virginia. Virginia Inst. Mar. Sci., Virginia Sea Grant Ed. Ser. No. 24). Since the inception of the VIMS sea turtle research program in 1979, 28 stranded leatherbacks have been recorded from Chesapeake Bay and Virginia's Atlantic coast, and one live leatherback was tagged. On 30 May 1985 the live leatherback was captured in a pound net at the mouth of Mobjack Bay (within Chesapeake Bay), situated between Virginia's York and Rappahancock Rivers. The turtle measured 133.4 cm CL and was assumed to be an adult female. The turtle was tagged on the rear flippers with monel tags (Center for Sea Turtle Research, Univ. Florida) and released in the York River. On 22 July 1986 the turtle was captured and killed by local fishermen in the Gulf of Guacanayabo, off southern Cuba. Tags were sent to the Center for Sea Turtle Research, but no other data were reported.

This is the first record of a leatherback moving from temperate waters to tropical nesting grounds, a minimum distance of 2168 km. The data support Lazell's suggestion (op. cit.) that leatherbacks travel directly between temperate latitudes and nesting (and probable mating) areas.

The turtle was measured and tagged by S. Bellmund, R. A. Byles, and R. Klinger. The Cuban Fish Ministry and J. A. Ottenwalder were involved in returning the tags to the Center for Sea Turtle Research. We thank R. A. Byles and K. L. Eckert for comments.

GRAPTEMYS CAGLEI (Cagle's Map Turtle). **Size.** Haynes and McKown (1974. Tulane Stud. Zool. Bot. 18:143-152) reported a maximum size of 161.1 mm CL for female *Graptemys caglei*. Killebrew and Porter (1989. Herp. Review 20:70) increased the previous record by 40.9 mm and noted substantial sexual dimorphism in size for this species. Recently, three females have been collected that exceed 202 mm CL, including two from the Guadalupe River above Canyon Lake in Comal Co., Texas and one from the Guadalupe River near Cuero, DeWitt Co., Texas. One of the Comal Co. specimens and the DeWitt Co. specimen were photographed and released. The other Comal Co. specimen, measuring 213 mm CL (mass = 1036 g), was deposited in the West Texas State University Museum of Natural History (WTSU 12535). These specimens were collected during a study funded by the Texas Advanced Research Program (Grant No. 1157) and a Research Enhancement Grant.

SAURIA

ANOLIS PORCATUS (Cuban Green Anole). **Behavior.** At 1100 h on 24 July 1990, agonistic behavior was observed between a large male *A. porcatus* (SVL ca. 65 mm) and a slightly smaller male *A. cybotes* near the eastern end of the Puente Duarte over the Río Ozama in Sto. Domingo, República Dominicana. This area has apparently only recently been colonized by *A. porcatus*. On a large tree trunk (ca. 35 cm diam), ca. 4 m above ground, the two lizards were situated ca. 20 cm apart, with the *A. porcatus* above. Both were perpendicular to the axis of the tree, but facing in opposite directions. Both animals were actively displaying with push-ups and extension of their dewlaps. As either moved, the other compensated in order to maintain the distance between them. At different times it appeared that both individuals initiated movement. This continued for over one minute before one or both lizards apparently became aware of the observer and both moved up the tree and out of sight.

Similar interactions between introduced *A. porcatus* and the ecologically similar Hispaniolan endemic *A. chlorocyanus* have been described by Arias C. (1975. Unpubl. thesis, Univ. Autonoma Sto. Domingo, 231 pp.) and Powell et al. (1990. Amphibia-Reptilia 11:*in press*), the latter suggesting that the presence of *A. chlorocyanus* may act as a constraint on the rate of range expansion by the larger and apparently more aggressive *A. porcatus*. Though the encounter with *A. cybotes* described here might well have been an unusual or isolated incident (no similar behavior has been observed at numerous other sites throughout Sto. Domingo where the species are sympatric), if potentially antagonistic behavior does occur between *A. porcatus* and *A. cybotes*, the presence of the latter might be an additional constraint on the rate of range expansion by *A. porcatus* in the Dominican Republic.

SERPENTES

ATHERIS NITSCHEI NITSCHEI (Sedge Viper). **Reproduction.** The sedge viper is an arboreal species found in the Lake Tanganyika region of equatorial Africa. Its range appears to extend from Uganda in the north to Zambia and Malawi in the south, and areas of western Tanzania and eastern Zaire. Published information concerning reproduction of this species has been scarce. Freed (1986. Herp. Review 17(2):47-48) reported on two litters of *A. chloroechis* from wild-caught females.

An adult group of 2.2 wild-caught specimens was received 2 November 1988 from a commercial source. Each snake was maintained individually in a 63 x 33 x 28 cm fiberglass unit provided with branches. On 24 May 1989, male A and female A were placed in a 61 x 45 x 41 cm fiberglass exhibit provided with live plants in addition to branches. Ambient temperature ranged from ca. 23° C to 27° C on a night/day cycle. Both precoital activity and copulation were noted during the first and second weeks of June. Copulation was again observed 1 August 1989. During at least one of these occasions, the temperature exceeded 32° C due to a mechanical malfunction. On 3 August 1989, female A was removed, and female B was introduced to male A; courtship behavior was noted almost immediately. Copulation was observed on 8 August 1989. Interestingly, female A had shed five weeks prior to her introduction to male A and did not experience ecdysis during her residence with male A. Two weeks after being isolated from male A, female A was again noted opaque.

By late November, female A was refusing food and was suspected of being gravid. On 9 January 1990, female A seemed listless and was found lying on the floor of the reserve. On 10 January 1990, female A was discovered with five live young and three undeveloped egg masses. Masses of neonates = 2.5 g, 4.4 g, 5.3 g, 5.7 g, and 6.3 g; X = 4.84 g. The smallest died within 24 h. Of the remaining four neonates, one shed within 24 h, two within 72 h, and the last one had to be assisted due to the shed becoming constricted at midbody.

The offspring apparently exhibit an ontogenetic color conversion, being almost black at birth with none of the bright green characteristic of adults. Like *A. chloroechis* (Freed op. cit.), the neonates have tail tips much lighter in color than the rest of the animal. When the juveniles shed at approximately ten weeks of age, their epidermal coloration abruptly resembled that of the adults.

I thank D. Herman for his comments.

CROTALUS SCUTULATUS (Mohave Rattlesnake). **Reproduction.** On 9 May 1984 a female Mohave rattlesnake was captured outside her individual den in western San Luis Potosí, Mexico, and removed due to the proximity to an agricultural operation. The habitat was a short shrub community composed mainly of *Haplopappus venetus*, with some *Sporobolus airoides*, *Distichlis spicata*, and *Bouteloua gracilis*. The site was located in rolling hill country, adjacent to a small dry-farmed plot. It was part of Rancho Las Joyas, Municipio de Villa de Ramos (22°6'30" Lat N; 101°44' Long W; 2120 m elev.).

On 31 August 1984 she delivered 17 young, four of which were stillborn. The young were measured and weighed at birth. X SVL = 211.6 ± 7.6 mm and X mass = 10.6 ± 0.9 g. The male:female sex ratio = 9:8. No intersex statistical differences were found.

THAMNOPHIS GIGAS (Giant Garter Snake). **Reproduction.** Virtually nothing is known concerning reproduction in *Thamnophis gigas*, a California Central Valley endemic recently elevated to specific status (Rossman and Stewart 1987. Occas. Pap. Mus. Zool. Louisiana State Univ. (63):1-25). *T. gigas* is the largest member of the genus, with a reported record TL of ca. 145 cm (Wright and Wright 1957. Handbook of Snakes of the United States and Canada. Comstock Publishing Associates. Ithaca, New York. 2 vols., 1106 pp.) and is listed as a Threatened Species by the State of California and a Category 2 Candidate Species for federal listing by the U.S. Fish and Wildlife Service.

During the course of recent and ongoing ecological and distributional studies of giant garter snakes (G. E. Hansen and Brode, 1980. California Dept. of Fish and Game, Inland Fisheries Endangered Species Program Spec. Publ. 80-5:1-14; R. W. Hansen 1980. Unpubl. M.A. thesis, California State Univ. Fresno. 78 pp.), eighteen gravid females were collected in Fresno and Sacramento counties and maintained alive in the laboratory for observation. All eighteen gave birth to live young, with relevant data shown in Table 1.

Cunningham (1959. Herpetologica 15(1):17-19) reported that a female collected July 24 (year not stated) from Buena Vista Lake, Kern Co., contained 24 eggs.

Table 1. Adult size, reproductive data, and size of neonates of *Thamnophis gigas*.

TROPIDOCLONION LINEATUM (Lined Snake). **Bird Attack.** Lined snakes are often observed in the yards of Richmond Heights, a suburb of St. Louis, Missouri. On 17 June 1960, a neighbor, Mr. George Heggs of the 7200 block of Arlington Dr., brought me an injured lined snake. At about 1600 h, he observed several blue jays (*Cyanocitta cristata*) pecking at this snake as it lay in the driveway. The pregnant female measured 27.3 cm SVL and 31.6 cm TL. The snake died.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19: 1–41), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 3: 802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. All specimen identifications *must* be verified by another authority (not one of the authors). Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to: Joseph T. Collins or Darrel Frost, Section Co-editors, Museum of Natural History — Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454 USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic Distribution: *Lampropeltis triangulum multistriata*. SSAR Herp. Review 25: 198.

Miller (Tennessee Permit 418), M. G. Donovan, & D. Donovan. Verified by G. Murphy. Middle Tennessee State University (MTSU 21C, 22C). New county record, extends known distribution into cedar glade ecosystem of middle Tennessee (Martof 1975, *Pseudotriton montanus*. Cat. American Amph. Rept. 166.1–166.2).

Submitted by **BRIAN T. MILLER**, Department of Biology, Middle Tennessee State University, Murfreesboro, Tennessee 37132. ●

ANURA

ELEUTHERODACTYLUS JOHNSTONEI (Johnstone's Piping Frog). LESSER ANTILLES: Grenadine Islands: Bequia Island, Friendship Bay. 6 & 8 December 1989. T. Sinclair. Verified by Ernest E. Williams & José Rosado. MCZ 114051, 114063. First record for the island (Schwartz & Henderson 1988, Milwaukee Pub. Mus. Contrib. Biol. Geol. 74: 22).

Submitted by **JAMES LAZELL** and **THOMAS SINCLAIR**, The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835. ●

HYLA AVIVOCA (Bird-voiced Treefrog). USA: ARKANSAS: Grant Co: 3.8 km W Leola at Cox Creek Lake, Sec. 28, T6S, R15W. 4 June 1990. John W. Robinette & Jase Goins. Arkansas State University Museum of Zoology (ASUMZ 16409–11). Ouachita Co: 5.9 km SW Chidester at White Oak Lake & Ark. Rt. 57, Sec. 33, T12S, R19W. 25 May 1990. Stanley E. Trauth & John W. Robinette. ASUMZ 16003–06. Union Co: Calion Lake at Calion, Sec. 15, T16S, R14W. 24 May 1990. Stanley E. Trauth & John W. Robinette. ASUMZ 16007–15; 16080. All the above records verified by V. Rick McDaniel. New county records (Davis & Hollenback 1978, Southwest. Nat. 23: 161–162; Turnipseed 1976, Herp. Review 7: 178–179; Turnipseed 1980, Herp. Review 11: 14).

Submitted by **STANLEY E. TRAUTH** and **JOHN W. ROBINETTE**, Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467. ●

TESTUDINES

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). USA: NORTH CAROLINA: Wilkes Co: 10.6 km SE Wilkesboro. 5 June 1990. D. W. Herman & B. W. Tryon. Verified by A. L. Braswell. North Carolina State Museum of Natural Sciences (NCSM 30680). New county record. Extends range 60.8 km WSW nearest Surry County voucher (NCSM 15730), 21.1 km NW nearest Iredell County record (Herman & Weakley 1986, Herp. Review 17: 27), and 48 km NE nearest Burke County record (Herman & Short 1986, Herp. Review 17: 27).

Submitted by **DENNIS W. HERMAN**, Department of Herpetology, Zoo Atlanta, 800 Cherokee Avenue SE, Atlanta, Georgia 30315, and **BERN W. TRYON**, Department of Herpetology, Knoxville Zoological Garden, P. O. Box 6040, Knoxville, Tennessee 37914. ●

STERNOTHERUS MINOR (Loggerhead Musk Turtle). USA: FLORIDA: Highlands Co: Lake Huntley, Secs. 5 & 8, T37S, R30E. 11 May 1990. Walter Meshaka & Noreen Gallo. Verified by James Layne. Vertebrate Museum, Archbold Biological Station (ABS 1081). New county record extends range onto Lake Wales Ridge, 140 km S of Orange County localities (Iverson & Etchberger 1989, Florida Sci. 52: 119–144.

Submitted by **WALTER MESHAKA** and **NOREEN GALLO**, Archbold Biological Station, P. O. Box 2057, Lake Placid, Florida 33852. ●

TRACHEMYS SCRIPTA (Neotropical Slider). HONDURAS: ISLAS DE LA BAHIA: Isla de Roatán, West Bay. 24 November 1989. J. R. McCranie. KU 214779. Verified by Joseph T. Collins. Complete shell of recently deceased adult (carapace length 31.5 cm) collected alongside a small freshwater pond. First record for island. Reported previously from the Islas de la Bahía on the basis of a shell in possession of a resident of Isla de Utila (Wilson & Hahn 1973, Bull. Florida St. Mus. Biol. Sci. 17: 93–150). These authors also stated that "residents on Roatán ... report [that] no fresh water turtles occur ..." on the island. A live adult *Trachemys* was also seen on 23 November 1989 in the possession of a resident in Coxen Hole, Isla de Roatán. The turtle was reported to have been found on Isla de Roatán near Sandy Bay. I was shown two other small freshwater ponds on Roatán where turtles have been sighted. Apparently, *Trachemys* occurs in small numbers on Isla de Roatán, but is under pressure from the local people as a food source.

Submitted by **J. R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157. ●

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: MISSOURI: Laclede Co: Interstate Rt. 44 just N

Webster County line near Conway (DOR). 23 May 1983. James N. Stuart. Verified by R. D. Jennings. MSB 39519. New county record (Johnson 1987, The Amphibians and Reptiles of Missouri, Missouri Dept. Conserv., 368 pp.).

SAURIA

ANOLIS PORCATUS (Cuban Green Anole). DOMINICAN REPUBLIC: DISTRITO NACIONAL: Santo Domingo, E end of the Puente Duarte. 24 July 1990. R. Powell. Verified by J. S. Parmerlee, Jr. Bobby Witcher Memorial Collection (BWMC 4282), Avila College, Kansas City, Missouri 64145. This is the first record for the species east of the Río Ozama, which had been considered a barrier to further range expansion by this introduced species (Powell et al. 1990, Amphibia-Reptilia 11: in press).

Submitted by **ROBERT POWELL**, Department of Natural Sciences, Avila College, Kansas City, Missouri 64145. ●

ANOLIS SAGREI (Brown Anole). USA: FLORIDA: Bay Co: Panama City Beach, Barnacle Bay Mini-Golf, 11209 West Hgwy. 98. 13 May 1989, 5 May 1990. G. H. Means, R. C. Means & D. B. Means. Verified by David L. Auth. Florida Museum of Natural History (UF 78392–96). New county record and first record for Florida panhandle (W of Suwannee River); extends range ca. 205 km NW of closest published locality, Waccasassa Bay State Preserve in Levy County (Funk & Moll 1979, Herp. Review 10(3): 102). About 20 juvenile and adults were seen 13 May 1989 in 2 hours of casual observation, but in 3 hours of intensive searching one year later, only 8 were seen, indicating that low record temperatures in December 1989 may have killed many on the ca. 2000 m² habitat island surrounded by a large asphalt parking lot. Search of adjacent habitat (tourist beach strip) one block in all directions failed to turn up others. *Anolis carolinensis* (UF 78390–91) was present also, but less common. Information gained from the owner of the site indicates that *A. sagrei* probably was introduced in cabbage palms and dolomite boulders trucked in from central Florida when the site was constructed in 1985.

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute, 1313 North Duval Street, Tallahassee, Florida 32303. ●

ANOLIS TRINITATUS (Vincentian Anole). LESSER ANTILLES: Saint Vincent: Young Island. 29 November 1989. J. Lazell & T. Sinclair. Verified by Ernest E. Williams & José Rosado. MCZ 175147–57. First record for island. In life these lizards closely resembled Kingstown specimens, with some yellow as described for examples from Chateau-belair Island (Lazell 1972, Bull. Mus. Comp. Zool. 143(1): 79).

Submitted by **JAMES LAZELL** and **THOMAS SINCLAIR**, The Conservation Agency, 6 Swinburne Street, Jamestown, Rhode Island 02835. ●

EUMECES FASCIATUS (Five-lined Skink). USA: PENNSYLVANIA: Erie Co: on abandoned Penn Central Railroad bridge crossing at East Branch Conneaut Creek, 0.5 km N U.S. Rt. 6N. 24 April 1990. Mark Lethaby & Judy Tucci. Verified by C. J. McCoy. Two specimens, CM 119167 & 119168. New county record; extends range 17 km N in state (McCoy 1982, Amphibians and Reptiles in Pennsylvania, Carnegie Mus. Nat. Hist. Spec. Pub. 6: 1–91).

Submitted by **MARK LETHABY** and **JUDY TUCCI**, Lake Erie Research Unit, Pennsylvania Fish Commission, 2000 Lohrer Road, Fairview, Pennsylvania 16415. ●

GYMNOPHTHALMUS SPECIOSUS (Antillean Lizard). LESSER ANTILLES: Grenada: no other locality data. 9 July 1971. J. D. Hardy, Jr. Verified by Charles J. Cole & Robert P. Reynolds. USNM 192965. First record for the genus from Grenada.

Submitted by **P. E. VANZOLINI**, Museu de Zoologia, Universidade de São Paulo, Caixa Postal 7172, 01051 São Paulo, São Paulo, Brasil. ●

GYMNOPHTHALMUS UNDERWOODI (Antillean Lizard). LESSER ANTILLES: Guadeloupe: Raizet, Abymes. Date unknown. G. Cornely. Verified by Ernest E. Williams. MCZ 122220–21. Previously identified as *G. p. pleei*. Basseterre. 12–15 July 1985. R. I. Crombie & J. D. Hardy, Jr. Verified by Charles J. Cole & Robert P. Reynolds. USNM 283176–83. Previously recorded from only a single locality in Grande-Terre (Schwartz & Henderson 1988, Milwaukee Pub. Mus. Contrib. Biol. Geol. 74: 130). Dominica: no other locality data. 19 September 1980. R. I. Crombie. Verified by Charles J. Cole & Robert P. Reynolds. USNM 218174–79. First record for Dominica. Reported by Brooks (1983 SSAR Herp. Review 14(1): 31–32) as *G. p. pleei*.

Robert Sliwinski. Verified by M. A. Romano. INHS 10877. New county record; this species has a spotty distribution statewide (Smith 1961, Bull. Illinois Nat. Hist. Surv. 28[1]).

Submitted by **ROBERT SLIWINSKI**, Department of Biological Sciences, Western Illinois University, Macomb, Illinois 61455. ●

BOOK REVIEWS

Australian Reptiles & Frogs, by Raymond T. Hoser, 1989. Pierson & Co., Sydney ix + 238 pp.$49.50.

Color photography of amphibians and reptiles just keeps getting better and better, and it is the best feature of this book on the Australian herpetofauna. Moreover on pp. 199-201 the author reveals some of his photographic techniques.

The book is divided into three sections, the first a conventional but well written introduction to biology and classification of amphibians and reptiles. There are numerous photos of snakes engaged in activities such as feeding, skin shedding, copulation, and birth of young but few of lizards and frogs and almost none of turtles. Pictures of such things as a turtle nesting, a frog egg film, a bearded dragon flattening its body to catch the sun, or the communal nest of *Lampropholis* would have improved this section. More could be said of the odd life cycles of Australian frogs. The gastric brooding of *Rheobatrachus* is barely mentioned, and nothing is said of the transport of tadpoles in inguinal brood pouches by male *Assa* or the highly specialized tadpoles of such torrent frogs as *Nyctimystes dayi*.

The largest section is devoted to descriptions of species most likely to be encountered in Australia, those of special interest, and those most often kept in captivity. This isn't a field guide but will help identify most species. For each species there is an excellent color photo, often several, illustrating ontogenic or geographic variation, a range map, and a brief account of identifying features, habitat, and habits. There are gaps in coverage. Microhylids aren't mentioned at all, and two snake families get poor treat-

ment. Australia's sea snakes are a distinctive and diverse group of ecological and medical importance, yet only two species are illustrated, one the cosmopolitan *Pelamis* and the other an *Aipysurus* misidentified as *Lapemis hardwickii*. Typhlopids also get short shrift, presumably because they all look much alike, little is known of their biology, and authorities can't agree on how many Australian species should be recognized.

The third section deals with a variety of topics including collecting techniques, husbandry, photography, and conservation. The author is highly critical of some Australian regulations governing collection and keeping of reptiles and amphibians. He says (p. 203): "Activities by corrupt and misdirected fauna authorities have almost wiped out the amateur herpetological community." He also gives examples of cases where critical habitat for rare species goes unprotected in australia. A unique section is devoted to scenes of a wide variety of Australian landscapes where herptiles occur with lists of characteristic species. But he omits one of the richest - the town rubbish dump.

There is a fairly adequate list of references and a good index. The book is attractive and well bound.

A biologist or naturalist going to Australia and interested in the native wildlife would do well to make room for this book in his luggage. Anyone fortunate enough to have legally obtained Australian reptiles or amphibians for his live collection will also find it useful. Reading this book is an easy way for the desk-bound herpetologist to appreciate the richness of the Australian fauna and landscape; if he has been there, he is almost sure to see a picture of something he missed. However, those who anticipate intensive research on some segment of the herpetofauna will need to consult additional publications.

Fauna of Saudi Arabia, Volume 9, edited by W. Buttiker and F. Krupp. 1988. Pro Entomologia (Natural History Museum, Basel) and National Commission for Wildlife Conservation and Development, Riyadh, Saudi Arabia, 465 pp. SFr 153. Available from Karger Libri AG, CH-4009, Basel, Switzerland.

This attractive volume of the *Fauna of Saudi Arabia* is extremely useful to biologists, particularly those who are interested in the study of the fauna of the Arabian peninsula. It includes 18 papers in about 465 pages, treating different animal taxa from annelids to birds, and discussing different subjects of major concern to biologists.

It seems out of place to review publications on different taxa in *Herpetological Review*, however there are two important papers on the reptiles of Arabia. The first is a comprehensive review of the snakes of Arabia and represents the cornerstone of the volume. It occupies 282 pages, constituting more than half of the volume size. The second paper, six pages in length, presents some observations on lizards.

The volume starts with two papers on nature conservation in Arabia. The first, by Jungius, discusses the concept of national parks and protected areas. He emphasizes the necessity of formulating wildlife and nature conservation policies in the Gulf area, and gives several examples of applications in different countries. He suggests that establishing a system of nature conservation areas will rehabilitate disturbed ecosystems, provide various benefits to rural communities, and maintain values for future generations.

The second paper, by Buttiker, deals with nature conservation, particularly birds. Some methods are described for trapping turtle doves at three locations along the Red Sea coast of Saudi Arabia, and results of other investigations are discussed. The author concludes that the turtle dove has not attained the status of a rare or endangered species.

The paper by Erseus is the fourth in a series of contributions on marine Tubificidae from the Arabian Gulf. It describes a new species of annelid, *Heterodrilus maiusulus*, collected from hypersaline waters in the Gulf of Bahrain, NE Saudi Arabia. The paper contributes to baseline data on marine fauna of the Arabian Gulf.

The list of insects of Saudi Arabia includes an appendix of nine papers. Concerning the first paper by Matile-Ferrero, third by Jelink, fourth by Holzel, fifth by Wiltshire, sixth by Kamahwi et al., and seventh by Greathead, many species are described and illustrated in each paper. The list of keys is very useful. Photographs and diagrams are present in some papers, and those are most useful.

In the other three papers, by Jach and Guichard, diagrammatic illustrations and keys for the systematic list should be followed, as records only to species are insufficient.

In general, the authors have certainly done an excellent job in scanning the literature. This bibliography is extremely useful to entomologists.

The paper on the molluscs of the Red Sea, by N. Yonow, discusses the taxonomic status of the Phyllidiidae and describes the fourteen species of the genera *Phyllidia* and *Reyfria* occurring in the Red Sea. A key is given to enable identification using external morphological characters. A series of maps is also provided illustrating the distribution of each species within the Red Sea.

The most significant part of the paper by Al-Absy, on the goatfishes of the Red Sea, is the keys to the genera and species. These are simple and explanatory. The descriptions of the individual species follow the classical methodology adopted by ichthyologists at present. The morphometric characters embodied in the tables serve the purpose of distinguishing related species in general terms.

The part concerned with the reptiles of Arabia includes two parts, the first of which deals with the snakes of Arabia. This paper contains a large amount of information on diverse topics. The extensive data, the presentation of the results, and the review of the herpetological literature [about 440 references, from Linnaeus (1758) and Forskal (1775) to Gallagher (1971), Gasperetti (1977), Arnold (1986), and Leviton (1986)] indicate the highly intense and tireless efforts of John Gasperetti to produce this work which is really very rich and very thorough. I indeed acknowledge this with praise.

In Gasperetti's paper, 54 taxa are listed through 2136 records - 1291 provided by the author and 845 collected from the literature. A short note on the poisonous snakes and the comparative toxicity of their venoms is given. Ophidian senses, skeletal features and dentition, undulations and sidewinding locomotion, are all described. Similarly, pholidosis is discussed in relation to the numbers and arrangements of scales, scutes, or plates on the body.

Gasperetti presents in this comprehensive work a systematic list of the snakes of Arabia and identification keys to families, genera, and species. An illustrated description is given for each of the eight families, 38 genera, and 54 species recorded. An historical and chronological synopsis of the nomenclature, as well as a short note on the habitats, and special adaptations, is given for each species.

Seventeen tables clearly illustrate descriptive data and specific features. Scale patterns and distribution maps are presented in 135 sketches, and there are 20 plates of photgraphic pictures, one for fossil forms and 19 for common living species.

Gasperetti also provides physiographic descriptions of different areas in the Arabian peninsula. He reviews the last 9000 years, during which there was a possibility of exchange of flightless terrestrial faunal forms between Africa and Arabia. He also gives an account of the present zoogeography and snake distribution with the African, Asian, and European distributions.

The last part of the paper deals with conservation. In this part, the author directs attention to the importance of snakes in the food chains of various fauna, their role in rodent control, and the medicinal values of various snake venoms. He reports that 40 protected areas, both terrestrial and marine, have been established in Saudi Arabia for the protection of wildlife. He also adds that some neighboring countries have made considerable progress toward wildlife conservation and he hopes to instill this awareness in the governing bodies of other countries which are not yet so enlightened.

There are three appendices to Gasperetti's paper. In Appendix I, he writes an introduction to and presents the paper of Dr. H. Alistair Read on snakebites. This paper discusses the clinical features, first aid, and medical treatments of snakebites. In Appendix 2, he gives some geographic and collection data for each of the 54 recorded species. In Appendix 3, he summarizes the taxonomic data in table form, clearly illustrating the diagnostic features of the families, genera, and species.

William Ross provided the second paper on the reptiles of Arabia. He reports observations on three species of the lacertid genus *Mesalina* found in certain areas of eastern Saudi Arabia, though these species are probably common in other regions of the Arabian peninsula. A fourth species, *M. ayunensis*, may be common in some regions and is often sympatric with *M. adramitana*.

The author reports short notes on the distribution and habitats of the three lizard species, with special emphasis on their locations in different altitudes. A distribution map, three photgraphs,and a simple table illustrating some morphological differences are also provided. Unfortunately, the table lacks basic taxonomic criteria.

Only a single reference is cited in Ross's paper, though the cited work is an important contribution to the herpetological fauna of the area. Several references are available and should have been included. Nerertheless, Ross has provided a fairly good work, considering that he is not a professional herpetologist.

The article written by Jennings on the birds of the Farasan Islands, Saudi Arabia, is based on two days' observations on two of these islands, unpublished records of other observers, and a review of the literature. Special attention is given to breeding species. The author also presents notes on the topography and vegetations of the islands. He brings out some interesting points in his discussion, among them the low diversity of land birds and the importance of protecting the islands which are used by many migrant seabirds.

The last paper in the volume deals with medical zoology in Saudi Arabia. A.M. Ghandour reports on the diseases caused by imported livestock. Imported and indigenous livestock were examined for facioliasis, echinococcosis, cysticercosis, onchocerciasis, schistosomiasis, coenurosis, and naso-pharyngeal myiasis. The paper has four tables, three maps showing the distribution of parasitic, viral, and bacterial diseases, and a histogram showing the consumption of imported and indigenous livestock in Saudi Arabia. The author suggests measures to combat the possibility of disease importation, based on his own studies as well as those reported in the world literature.

This volume of Fauna of Saudi Arabia fills a major gap in the amount of information relating to many of the vertebrates and invertebrates found on the Arabian peninsula. It also contributes to the growing interest in the nature conservation concept and to the priority given for the preservation and development of wildlife populations in this region.

Biochemical Evolution in the Slimy Salamanders of the *Plethodon glutinosus* Complex in the Eastern United States, by Richard Highton, George C. Maha, and Linda R. Maxson. 1989. Illinois Biological Monographs 57, University of Illinois Press, 54 E. Gregory Dr., Champaign, Illinois 61820. 153 pp. $18.95.

It used to be so easy. Big, white spotted, black salamanders, that covered your hands with goo when you picked them up, were *Plethodon glutinosus*, whether you found them in Texas, Florida, or New York. This comfortable picture started to get more complex when Highton and MacGregor (1983) and Highton (1984) showed that three species (*Plethodon aureolus*, *P. teyahalee*, and *P. kentucki*) had been masquerading as *glutinosus* while coexisting sympatrically with it. Now Highton, Maha, and Maxson use biochemical data to demonstrate that what remained of *the* slimy salamander is actually a mosaic of 13 parapatric "groups" that hover around the species level of divergence and that Highton, in the initial (and major) section of this two-part monograph, formally names as semispecies. In the second, much briefer part, Maha, Maxson, and Highton show that differentiation among at least some of the *glutinosus* semispecies is also reflected in serum albumin structure. Since only three antisera were available, they are unable to independently confirm Highton's much more extensive electrophoretic analyses.

Highton's methodology is straightforward. He constructs, on the basis of 22 presumed allozyme loci, a matrix of Nei genetic distances among 135 populations from throughout the range of the former *Plethodon glutinosus*. From this he derives a standard UPGMA phenogram indicating that at a Nei distance of about 0.15 the populations cleave into a series of 16 geographically cohesive "groups." Three of these (*aureolus*, *teyahalee*, and *kentucki*) are previously recognized species that occur sympatrically with at least one other *glutinosus*-like salamander; the remainder are recognized and named as subspecies. The large amounts of uninformative variation precluded cladistic analyses, but Wagner distance trees confirm the existence of several distinct groups of populations, while indicating somewhat different evolutionary relationships. The discrepancies between the UPGMA phenograms and the Wagnertrees are ascribed to variation in evolutionary rates, brought about at least in part to gene exchange between some of the groups.

This work convincingly demonstrates the power of biochemical data to reveal genetic sub-structuring, but may strike many "traditional" systematists as biochemistry run amuck. Highton enthusiastically confronts these apprehensions, particularly Wake's (1981) assertion that recognizing allopatric species solely on the basis of allozyme data will generate taxonomic "chaos." He argues convinc-

ingly that allozyme data reveal more about evolutionary relationships among morphologically conservative organisms than conventional taxonomic characters but his tone, and implication that reluctance to name taxa on the basis of biochemical characters owes to intellectual inertia, seems unnecessarily confrontational. In fact, the effort that Highton expends in justifying his approach seems a bit misplaced.

For one thing, this taxonomic subdivision of a widely-distributed salamander species shouldn't surprise students of plethodontid systematics. We've known for some time now that the morphological conservatism of the genus *Plethodon* often masks deep evolutionary divergence, that human sensory systems don't perceive the signals that salamanders themselves use to tell their species apart, and few of us believe that taxonomic arrangements should sacrifice accuracy for simplicity. More importantly, Wake's vision of taxonomic chaos (1981:262) pertained to uncritically applying "taxonomic consistency rules" based on biochemical data, i.e. defining species *solely* as groups of populations that cluster at some accepted, perhaps arbitrary level of genetic similarity.

Highton's objective in selecting a particular Nei D to discriminate between semispecies was to create taxa that represent parapatric, geographically cohesive, and (in at least several cases) reproductively isolated units. His analyses indicate that among- and within-group associations between D and geographic distance appear weak (but are never quantified). Thus the groups are portrayed as genetically homogeneous, apparently "natural" units. They certainly appear highly differentiated: only 7 of 120 between-group comparisons (and only 3 of 26 mean D's between parapatric forms) yield Nei distances below 0.20. The boundaries between the groups generally appear to be quite sharp, at least as Highton portrays them, with little evidence of hybridization (but genetic studies of contact zones are currently underway and only a few data on this critical point are presented here). There *are* body size and color pattern differences between some of the forms, and now that we know what the subdivisions are, careful morphological studies are likely to reveal more. The species complex that emerges from these studies is highly, fascinatingly structured, and certainly not chaotic. By revealing this structure Highton, Maha, and Maxson have made a major contribution to North American herpetology.

Given the staggering amount of work that this study represents (the collection and processing of nearly 4000 animals from 135 localities across the entire eastern U.S., 8 years spent running and rerunning countless gels), there are several points that warrant more rigorous treatment. Brief mention is made (p. 43) of the failure of the 16 forms (called "species" in this paragraph) of the *glutinosus* complex to form a monophyletic clade, but no cladograms or other details relating to this tantalizing finding are presented. The association between genetic distance and geographic distance, so critical to evaluating the vision of broadly distributed parapatric units, is never accorded a thorough quantitative treatment, via such tools as Mantel tests, hierarchical F statistics or spatial autocorrelation analysis.

Evidence for hybridization between *glutinosus* and parapatric semispecies is mentioned on p. 35, but no data are presented. Instances of gene exchange among semispecies are again mentioned on p. 53, without mention of which taxa are involved. The term "hybridization", in fact, isn't in the index. One is left wondering whether Highton's views derive as much from his "feel" for these animals as from quantitative analyses, and hoping that his studies on gene exchange between the semispecies will be published soon. Finally, it is difficult to find which forms occur in a particular geographic area, because the only figure (Fig. 5) displaying the ranges of all the forms shows neither scientific names nor political boundaries; none of the maps have scales or compasses, and dot maps are lacking for several forms.

Highton states that "...in this one complex...we find many of the problems that have troubled taxonomists in defining the limits of species." His taxonomic treatment attempts to deal with the familiar problem of parapatric populations that have evolved varying levels of differentiation and reproductive isolation. He admits that other authors might choose to recognize his semispecies as subspecies, if at all, but meanwhile we're faced with seven new (*chattahoochee*, *ocmulgee*, *kiamichi*, *mississippi*, *kisatchie*, *sequoyah*, *savannah*), and five resurrected (*chlorobryon*, *variolatus*, *grobmani*, *cylindraceus*, *albagula*) names, all with attendant synonymies, type descriptions, holotypes, allotypes, paratypes, etc. The epithet *glutinosus* now refers to a species group, a species complex, a species, and a semispecies.

All this new nomenclature emerges, not from the uncritical use of biochemical data, but from a deeply traditional approach to systematics. Thus the search for a Nei distance that provides the sorts of geographically cohesive, allopatric groups that incipient species are supposed to be. A traditional, "biological" species concept necessitates discussion of reproductive isolation, even though few data are available and some systematists regard them as irrelevant to defining species in the first place (Otte and Endler 1989). Evolutionary divergence is summarized largely by naming, describing and mapping taxa. One can deeply admire this work while wondering what all the nomenclature really adds to our understanding of these animals. Those "old fashioned systematists" willing to accept the utility of biochemical data will find much here that they like.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to rtteview herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations and photographs. Manuscripts submitted must be typed, double spaced, on 8.5X11 inch paper, and should be sent in duplicate. We encouregе submissions on Macintosh disks, though we can also work with TEXT (ASCII) files submitted on IBM and compatible floppies. **Herpetological Review** is composed on a Macintosh SE using Microsoft Word, which accepts files from several other word processor applications. Format your documents full-page width; we will fit to **HR** format. Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8X10 inches black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. Herpetological Review will accept commercial advertising. Rates and copy information are available from the advertising manager. Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats. Contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

Society For The Study Of Amphibians And Reptiles

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (4 issues annually), **Herpetological Review** (4 issues annually), and occasional issues of **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1990

Student member.....$25.00*	Sustaining member.....$50.00*
Regular member.....$35.00*	Contributing member.....$75.00*
Institutional subscription.$60.00*	Life member..(see below)...$600.00*

***Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, draft on a US bank, or by Mastercard or Visa (include account number and expiration date of credit card). Life memberships may be paid in 3 consecutive payments

Subscriptions to Herpetological Review only are available for $12.00 annually. Subscriptions outside of the US require a surcharge of $8.00 for air delivery if airmail is desired. Subscribers to HR only are not members of the Society.

Catalogue of American Amphibians and Reptiles: subscription $15 annually ($3.00 air delivery surcharge if airmail is desired.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc., RFD 6 Box 1, Lawrence, KS 66046. Steve Meseraull, Printer. SSAR BUSINESS

SSAR GRANTS-IN-HERPETOLOGY

Proposals now are being accepted for the 1991 SSAR Grants-in-Herpetology Program. This program is designed to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. In keeping with the Society's goal of encouraging participation of the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR, with the exception of those applying in the REGIONAL HERPETOLOGICAL SOCIETY category. Applicants are limited to submission of one proposal in one category per year. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Grant proposals will be considered in the following categories:

1. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address educational projects, speaker's fees, regional research, defrayment of one-time-only costs, or other purposes that would strengthen regional societies. Proposals may be submitted by regional herpetological societies or by individual members and must be accompanied by a letter of support from the current president of the regional society.

2. HERPETOLOGICAL RESEARCH OR EDUCATION IN ZOOS. Proposals may address any herpetological endeavor conducted in zoos, such as improvement of displays, husbandry, or behavioral research.

3. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species. Proposals must be from individuals only and must be accompanied by a letter of support from another member of the SSAR.

4. FIELD WORK. Proposals may address support for travel to ecological study sites or for survey collections. Proposals normally submitted in the CONSERVATION or GRADUATE STUDENT RESEARCH categories, but for travel (or field station) support, should be submitted here. Proposals for survey collecting are appropriate for this category. Proposals must be from individuals only and accompanied by a letter of support from another member of the SSAR.

5. GRADUATE STUDENT RESEARCH IN HERPETOLOGY. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only. Applications must be accompanied by a letter of support from the student's major advisor or committee chairperson.

Each proposal must include the following: (A) BACKGROUND AND OBJECTIVES of the proposed project. (B) METHODS of carrying out the project. (C) BUDGET, which should not exceed $400. (D) BRIEF RESUME of the applicant or project coordinator. (E) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages, excluding resume and budget.

Applicants must designate to which of the five categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted in duplicate and postmarked no later than 31 January 1991. Failure to meet the guidelines may result in elimination of a proposal from consideration. The awards will be announced by 1 April 1991. Successful applicants will be expected to submit to the SSAR a written report of the result of this support within a reasonable amount of time after the project year is completed. They also are encouraged to submit the results of research projects for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regard application procedures to:

Darrel Frost, Chair (212-769-5852)
SSAR Grants-in-Herpetology
Committee
Department of Herpetology
American Museum of Natural History
Central Park West at 79th Street
New York, NY 10024, USA

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number of awards in this program. Your tax-deductible contribution to this program will benefit directly meritorious research and education in herpetology. Contact the President of the SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program. ●

ANNUAL REPORT 1990 SSAR GRANTS-IN-HERPETOLOGY COMMITTEE

Committee: D. Belcher, T. Fritts, D. Frost (Chair), J. Johnson, M. Plummer, H. Quinn, E. Rundquist.

In 1990, the Grants-in-Herpetology Committee made six awards in four categories:

Graduate Student Research: (1) Cindy Taylor, Department of Biological Sciences, Mississippi State University. Proposal title: "The effect of oral-disc morphology of anuran tadpoles on grazing selectivity of algae." Award: $300.00; (2) Calvin Porter, Department of Biology, Texas Technological University. Proposal title: "Containment of transposable elements in unisexual lizards." Award: $300.00.

Fieldwork: (1) Philip Robakiewicz, Department of Ecology and Evolutionary Biology, University of Connecticut. Proposal title: "Physiological and behavioral correlates of aggression in the dart-poison frog, *Dendrobates pumilio* Schmidt." Award: $300.00; (2) Stephen M. Secor, Department of Biology, UCLA. Proposal title: "Foraging mode as a determinant of energy expenditure in desert snakes." Award: $300.00

Regional Society: Virginia Herpetological Society (Joseph C. Mitchell and Kurt Buhlmann). Proposal for support of a promotional poster for the Virginia Herpetological Society. Award: $300.00.

Conservation: Stephen Nyman, Department of Zoology, University of Rhode Island. Proposal title: "A comparative study of surface activity, movements, and microhabitats of the Larch Mountain Salamander, *Plethodon vehiculum*." Award: $300.00. ●

HR PERSONNEL CHANGES

There have been two changes in *Herp Review* staff during 1990. Alvin Braswell of the North Carolina State Museum of Natural Sciences resigned as Section Editor for Geographic Distribution, after ably serving in that position for almost three years. We thank Alvin for the outstanding job he has done as Section Editor, a job which requires abundant correspondence with authors, skillful editing, and, oftentimes, many hours in the library checking records. Geographic Distribution records now should be sent to either of the new Section Editors, Joseph T. Collins or Darrel Frost (see inside front cover).

In 1990, Raymond J. Stein, *HR* Advertising Manager for the past seven years, resigned from this position. During his tenure, Ray did an exceptional job of working with our advertisers, serving as liaison between advertisers and the editor, and maintaining the books for this very important aspect of our publication. All matters concerning advertisements in *HR* now should be sent to the new Ad Manager, Elizabeth Johnson, at the New Jersey Field Office of the Nature Conservancy (see inside front cover).

The Society (and the Editor!) extend their gratitude to Alvin and to Ray for their years of service and wish them well in their future endeavors. We also thank Joe Collins and Liz Johnson for assuming their respective duties. ●

DESK TOP UPDATE

This issue of *Herpetological Review* is the first to have been "typeset" and composed entirely by desk top publishing. The groundwork for this advance was laid by George Pisani, who experimented with the technology over the past few issues. Tom Tyning served as Desk Top Managing Editor for this issue, and Christine L. Dwyer, Robert W. Hansen, and Carole L. Hom converted typed copy to disk. Through the volunteer efforts of these SSAR members, a significant amount of money is being saved. This will enable us to publish a larger number of pages on a regular basis, thus reducing turnaround time for manuscripts.

NEEDS. **1**. The more volunteers keystroking manuscripts onto disks, the less tedious it is for each volunteer. If any readers have a Macintosh, can use Microsoft Word 4.0 (or similar software), are willing to keystroke a few pages per month onto disk, and are willing to give this a high priority (i.e., begin keystroking shortly after receiving a manuscript from the editor), please contact the editor [phone (216) 368-3558 (work) or (216) 354-1430 (home)]. **2**. Authors should make every effort to submit their manuscripts on Macintosh disks, preferably in Microsoft Word. Other formats may be acceptable; for specific information, call Desk Top Managing Editor Tom Tyning at (413) 443-9201 (work) or (413) 442-2165 (home). ●

CALL FOR STUDENT PROPOSALS

The **Gopher Tortoise Council** is seeking proposals from undergraduates and graduate students who are planning or actively conducting research on the gopher tortoise (*Gopherus polyphemus*), its habitat, or its burrow commensals. A maximum of $500.00 is available.

Proposals should be no more than four typed, double spaced pages and should include a description and justification for the research, a budget indicating how the money will be spent, and a brief biographical sketch.

Proposals should be submitted to Dr. Bob Herrington, Student Awards Coordinator, Department of Biology, Georgia Southwestern College, Americus, GA, 31709, USA. (912) 928-1617. ●

1991 SSAR MEETING

The 1991 meeting of the SSAR will take place 7-11 August at Pennsylvania State University, University Park, PA. Contact: Dr. Linda R. Maxson. Further information will appear in the December issue of *Herp Review*. ●

NEWSNOTES

COLLECTIONS TRANSFERRED TO FLORIDA MUSEUM OF NATURAL HISTORY

The Herpetology Division of the Florida Museum of Natural History in Gainesville, Florida has acquired part of the library of Archie F. Carr, consisting of nearly 4,400 reprints on herpetological subjects other than sea turtles (his sea turtle library is housed at the Archie Carr Center for Sea Turtle Research, Zoology Department, University of Florida). The division has also acquired the specimen collection and library of Lewis D. Ober, retired professor in the Department of Biology, Miami-Dade Community College North Campus (7,300 specimens; 1,850 reprints, journal numbers, and books). The major emphasis of the Ober Collection is the West Indies. ●

MEETINGS

WILDLIFE 2001: POPULATIONS

Wildlife 2001: Populations is an international conference intended for research workers and agency personnel whose interests are the science, conservation, and management of vertebrate populations (exclusive of fish and primates). Papers will assess the state of the art and set the agenda for applied wildlife population work on the verge of the 21st century. It is a followup of the highly successful Wildlife 2000, which emphasized habitat modelling, and a companion publication will be produced.

The conference will be held 29-31 July 1991, at the Oakland Airport Hilton Hotel

in Oakland, California. This hotel is a low-rise hotel with outside courtyards and gardens, and is away from the downtown area, within a mile of the Oakland Airport. Free parking and free shuttle buses to the airport and rapid transit (BART) give easy access to the greater San Francisco Bay Area.

Morning general sessions, with chairs, will be: Methods, Gary White; Modelling, Carl Walters; and Threatened Species, Kathy Ralls. Afternoon sessions include: Small Mammals, Lloyd Keith; Marine Mammals, Chuck Fowler; Waterfowl, Doug Johnson; Overabundant Populations, Fred Wagner; Herps, Norman Scott; Large Herbivores, Fred Bunnell; Game Birds, John Roseberry; Seabirds, David Nettleship; Passerine Birds, Barry Noon; Large Carnivores, Maurice Hornocker; Raptors, Stan Temple; and Furbearers, Bill Clark.

Initial sponsors include the Bay Area Chapter of The Wildlife Society, and Department of Forestry and Resource Management, University of California.

For further information contact the conference organizers, Dale McCullough (415) 642-8462 or Reg Barrett (415) 642-7261, Dept. of Forestry and Resource Management, 145 Mulford Hall, University of California, Berkeley, CA 94720, USA (Fax 415/643-5438). ●

CALL FOR PAPERS
1991 IHS

The 1991 International Herpetological Symposium on Captive Propagation and Husbandry (IHS) will be hosted by the Pacific Northwest Herpetological Society and will be held in Seattle, Washington. The meeting will be held 20-23 June, at a location to be announced.

Program Chair for this meeting is Dr. Richard Ross. Any herpetologist wishing to present a paper or lead a workshop at this meeting should contact Dr. Ross at: The Institute for Herpetological Research, PO Box 2227, Stanford, CA 94305, USA. Tel: (415) 941-4595 (day, Pacific Time). The deadline for submission of abstracts/titles is 1 January 1991. ●

CONFERENCE ANNOUNCEMENT

The 6th Annual Meeting of the Society for the Preservation of Natural History Collections will be hosted by the Canadian Museum of Nature in Ottawa, 6-11 May 1991. The program will include: council and committee meetings, technical sessions and tours (6 May), a three-day annual conference (7-9 May), and a two-day training workshop on "Practical Approaches to Preventive Conservation for Canadian Natural History Collections" given by the Canadian Conservation Institute (10-11 May).

For information, contact: G. R. Fitzgerald, Canadian Museum of Nature, Earth Sciences (Paleobiology), P. O. Box 3443, Station D, Ottawa, Ontario, KIP 6P4, CANADA. ●

REGIONAL SOCIETIES

ADDRESS CHANGES

The following new societies/address changes have been submitted since the list of herpetological societies was printed in the June 1989 issue of *Herpetological Review*:

Herpetological Association of
Zimbabwe
c/o Alice Lane
Avondale, Harare
Zimbabwe
AFRICA

Herpetological Society of Cyprus
P. O. Box 2133
Paphos, CYPRUS

Pacific Northwest Herpetological
Society
P. O. Box 70231
Bellevue, WA 98007, USA

Southwestern Herpetologists Society
P. O. Box 7469
Van Nuys, CA 91409, USA

Society officers are encouraged to forward to the SSAR Regional Society Liaison (see inside front cover of *HR*) any address changes for their society. Newly formed societies are invited to announce their existence in this column, and established societies are invited to submit short descriptions of their organization for publication in this column. ●

LEGISLATIVE ALERT

This column is produced by the SSAR Conservation Committee to alert members of the herpetological community to recent and proposed regulatory changes involving reptiles and amphibians. We encourage SSAR members to notify us of any significant changes in state, national, or international conservation laws as they relate to these animals. For further details about any of the following, or to report additional changes, please contact Kurt Buhlmann, SSAR Conservation Committee, c/o Virginia Natural Heritage Program, Department of Conservation, 203 Governor Street, Richmond, VA 23219, USA.

The following final and/or proposed listings and regulations have been announced by governmental regulatory agencies. Pertinent Federal Regisater 90 citations are given for U.S. notices.

U.S. ***Gopherus agassizii*** (desert tortoise), Mojave population only; final rule, Listed as Threatened [FR 55(63):12178-12191, 4/2/90]

The Mojave population covered by this rule includes all tortoises north and west of the Colorado River in CA, southern NV, southwestern UT, and northwestern AZ. Present status is chiefly the result of habitat destruction and degradation as a result of development, agricultural conversion, grazing and off-road vehicle use. The continued existence of this population also is threatened by illegal collection, an upper respiratory disease, excessive predation of juvenile tortoises by common ravens, and other factors.

U.S. ***Phrynops hogei*** (Brazilian = Hoge's sideneck turtle); proposed as Endangered [FR 55(80):17469-17473, 4/25/90]

This rare chelid is native to the Rio Paraiba and Rio Itapemirim drainages in southeastern Brazil. Extensive deforestation in the past 20 years has left the banks and marshes of both drainages unsuitable for freshwater turtle habitation and reproduction. Recent field collections have failed to find any juveniles.

U.S. ***Trachemys scripta callirostris*** (Colombian slider = South American red-lined turtle); proposed as Endangered [FR 55(80:17469-17473, 4/25/90]

This subspecies was once common in Caribbean drainages in northern Colombia and northwestern Venezuela, but

habitat destruction from burning, development, and conversion for petroleum facilities may have extirpated many populations. Adults, eggs and hatchlings are exploited for human consumption and the pet trade.

U.S. ***Trachemys stejnegeri malonei*** (Inagua Island turtle); proposed as Endangered [FR 55(80):17469-17473, 4/25/90]

This subspecies of central Antillian terrapin inhabits only Great Inagua Island. Threats to its freshwater habitat include consumption of fresh water by an expanding human population and the possible expansion of solar salt processing operations.

U.S. ***Trachemys terrapen felis*** (Cat Island turtle); proposed as Endangered FR 55(80):17469-17473, 4/25/90]

This emydid occurs only in freshwater ponds on Cat Island in the Bahamas. All but one known site have been degraded by agricultural burning or excessive human use, and the total population appears to have dwindled.

The SSAR Conservation Committee has notified the USFWS that Seidel (1988) formally sank this taxon, which he believed to represent an introduction of *T. terrapen* from Jamaica.

U.S. ***Cnemidophorus vanzoi*** (Maria Island ground lizard); proposed as Endangered [FR 55(80):17469-17473, 4/25/909]

Now restricted to the islets of Maria Major and Maria Minor, off St. Lucia, this teiid was probably extirpated by introduced rats and mongooses from the mainland of St. Lucia before specimens could be documented. Fewer than 1000 individuals are believed to remain on 30 acres of habitat.

U.S. ***Boiga irregularis*** (brown tree snake); importation or shipment prohibited without permit (4/25/90)

The USFWS has added this non-indigenous colubrid to its list of injurious live reptiles. Importation, acquisition or transportation of any live specimens or eggs between the continental U.S., the District of Columbia, Hawaii, Puerto Rico, the Northern Mariana Islands or any territory or possession of the U.S. is prohibited. Introduced brown tree snakes on Guam have resulted in a precipitous decline in the endemic avifauna of the island and also pose other detrimental effects to agriculture and human health and safety.

U.S. ***Liophus ornatus*** (Maria Island Snake); proposed as Endangered [FR 55(80):17469-17473, 4/25/90]

Extirpated from St. Lucia for most of the twentieth century, presumably by introduced rats and mongooses, this small snake is now restricted to the adjacent islet of Maria Major, where as few as 100 individuals may survive.

Florida Commercial Sale of native reptiles and amphibians or products thereof; permit required.

In an attempt to monitor the commercial trade in the state's native herpetofauna (both as pets and as consumptive products), the Florida Game and Fresh Water Fish Commission will require all dealers to obtain a no-cost permit and to prepare periodic reports documenting sales of native amphibians and reptiles and their parts.

Dale R. Jackson, Chair
SSAR Conservation Committee ●

FEATURES

THE STATUS AND DISTRIBUTION OF THE HELLBENDER, *Cryptobranchus alleganiensis* IN OHIO.

Barton (1812) provided the first account of the hellbender in Ohio when he reported it from the Muskingum, Miami, and Scioto Rivers. Kirtland (1838) correctly said that it "is found in all the tributaries of the Ohio but not in those of Lake Erie." By 1985 hellbenders had been reported from 48 localities in Ohio representing all the major systems draining into the Ohio River. These localities are represented by less than 70 specimens. Most of the records were obtained by fishermen or were collected incidentally to some other effort such as seining or bait collecting. Other than locality records, there is little information available on hellbenders in Ohio. In an effort to determine the status and distribution of hellbenders in Ohio, the Ohio Department of Natural Resources funded the present study so that an effective management plan could be prepared for this species.

METHODS AND MATERIALS

Microhabitat requirements of hellbenders were first determined by visiting localities where specimens had been most recently collected. All of the known localities within the state were subsequently explored, and a systematic study of all topographical maps was undertaken to identify suitable habitats. Every stream with a watershed of 260 square km (100 sq. mi) or greater was checked, except for the largest rivers where the silt load and depth made work impossible.

The most productive habitat included riffle areas 60 cm or less in depth with large, flat slabs of rock on a substrate of sand or gravel. No animals were found under any rocks that were less than ca. 50 cm in diameter nor were any animals found under objects other than rocks. We never found more than one hellbender under a single slab although on one occasion a hellbender and a mudpuppy were found in separate compartments under a 1 m diameter slab.

In unfamiliar watersheds we began in the headwater regions and worked our way down stream until sufficient flow and suitable habitat was found. One technique that was found to be particularly useful was studying topographical maps in search of places where a stream took a sharp turn against a hill. The logic that a stream cutting into a hill caused slabs to tumble into the stream bed proved useful as often this was the only place where rocks could be found in a particular stream.

An attempt was made to locate hellbenders utilizing electroshocking apparatus according to a method described by Williams, Gates and Hocutt (1985). However, we were unable to successfully reproduce their efforts and this technique was abandoned during the final year of the project.

Temperature, pH, and general stream conditions were noted at each locale. Slab rocks were systematically turned, beginning at the downstream end of an area. Slabs were turned into the current whenever possible so that silt would be carried away. Ordinary cotton work gloves allowed a better grip on larger rocks and hellbenders as well.

Total length (Fig. 1) and standard length were recorded for each animal using an

ordinary transparent plastic thistle seed bird feeder. This provided restraint without stressing the animal. During the breeding season (August to mid-October) the area surrounding the vent of the male becomes greatly enlarged. This was the only time when animals could be accurately sexed. The general condition of the animal was noted including distinctive scars and missing limbs and parts of limbs. Each animal was tagged with a numbered Floy T-tag through the dorsal fin of the tail. It was then released back into the stream usually next to the rock where it was captured.

RESULTS

One hundred twenty-one animals were tagged over the course of this study (Fig. 1). Eighty were captured or recaptured during the breeding season and could be reliably sexed. Sixty-two of the animals were males and 18 were females. This unbalanced ratio in favor of males is similar to other findings in the east. In Pennsylvania, for example, Smith (1912) reported a male : female ratio of 2:1 to 3:1, and Hillis and Bellis (1971) reported a 1.58:1 ratio. Males averaged 51.2 cm in total length while females averaged 51.7 cm.

Animals were found in streams where the water temperatures ranged between 0° C and 33° C. The pH was between 6.0 and 9.2 while water clarity ranged from opaque to clear to a depth of 1 m.

Most of the new populations (Fig 2) were discovered during 1988 subsequent to the preparation of *Salamanders of Ohio* (Pfingsten and Downs 1989). The 1988 discoveries were directly attributable to the effects of the drought that year. Not only were streams shallower and narrower as a result of the drought, but the silt reduction and clarity made it possible to work in streams where even brief summer showers ordinarily kept them too turbid to work. In addition, water temperatures were unusually high in 1988. A young male was found in water at 33° C. This is close to the upper limits of temperatures reported in nature for this species (Nickerson and Mays 1973) and close to the critical thermal maximum for the species (Hutchison et al. 1973).

In an attempt to estimate population density in the West Fork of Little Beaver Creek we tagged 54 animals in a 120 m long riffle during 16 visits to the area. Eight animals were recaptured and one of these was recaptured a second time. The interval between capture and recapture ranged from 40 days to 358 days. All recaptures were made in the immediate vicinity of the original capture. Because of the small number of recaptures, no estimate of population size was made.

On two visits in August 1987, this riffle was worked with a crew of 6 - 9 people. Almost every rock in that stretch of stream was turned and it was felt that nearly every animal in the riffle was captured. On the first visit we captured 11 animals and on the second we found 10. At least on these occasions the density was ca. one animal for every 350 sq. m of riffle.

There are no records or literature accounts of hellbenders being captured during the coldest part of winter in the northern part of their range. It was decided that if good weather occurred an attempt would be made to find some hellbenders. On 23 December 1986 it was sunny and calm and the air temperature was 7° C. Previous to this there had been several days of subfreezing temperatures. The West Fork of the Little Beaver Creek was low, clear and 0° C. Ice had formed along the shoreline and quiet areas of the stream and small chunks of ice and slush covered most of the flowing surface of the stream. A large male (TL=58 cm) was found curled under a rock slab in the center of the riffle. When removed from the water, he was so stiff that it took several minutes to straighten him out so that he would fit into the measuring tube.

The largest hellbender found was a male with a total length of 63 cm. When captured, on 27 September 1986, the animal was placed in a bucket. Within a few minutes it regurgitated a complete frog skeleton. The skeleton was in perfect condition an no flesh remained on the bones. Total length of the skeleton was 255 mm, and was most likely that of a bullfrog, *Rana catesbeiana*. Bullfrogs and the green frog, *Rana clamitans*, are common in the area. There are no literature accounts of frogs being eaten by hellbenders in the wild although they are known to take frogs in captivity (Smith 1907).

The only complete hellbender nest reported for Ohio was discovered on 21 September 1986 (photo in *Salamanders of Ohio*, Pfingsten and Downs 1989). The nest contained ca. 250 eggs, was found under a slab measuring 132 cm x 74 cm x 21 cm, and appeared to have an opening on the downstream side of the rock.. The rock was partly out of the water and within one meter of the shore. At that point the main flow of the stream was along the shoreline. The depth of the egg cavity under the slab was 38 cm and it was ca. 35 cm in diameter. A large male (TL=54 cm) was lying on the bottom of the cavity beneath the egg mass. When the male was captured and placed in the bucket, four eggs were expelled from the gill slits indicating that he had been cannibalizing the egg mass. Slightly more than half of the eggs were fertilized and had developing embryos. They appeared to be similar to the 18 day embryos shown by Smith (1907).

Twenty-five percent of all the animals we saw had some sort of injury. Eighty percent of the injuries involved missing toes, feet and limbs. Other injuries included scrapes to the top of the head, gashes to the flanks and tail and at least one had scars on the snout and face which looked like the bite from another hellbender.

Nickerson and Mays (1973) reported than many injuries may be caused by canoes as they strike rocks during periods of low flow. In Ohio, however, the injuries were apparent in all populations including those from streams which are too small for canoeing. Animals with fresh wounds were seen only during August and September and may have been the result of battles during the breeding season.

DISCUSSION

No animals were found west of the Scioto River except for Scioto-Brush Creek. Further, no animals were found in the Ohio River, a result that was not unexpected. The completion of the high dam projects in 1965 raised the level of the river ca. 3 m, eliminated all riffle areas, and changed the environment from that of a river to one resembling a lake.

No larvae were found during the study. The rather unusual population structure of hellbenders is weighted heavily towards old adults. Because of their longevity of 30 or more years (Taber et al. 1975), low population density, and lack of natural predators as adults, there are few replacement young needed in the population. The rarity of larvae has been reported by Swanson (1948), Hillis and Bellis (1971), and Taber et al. (1975). Larvae are either occupying some yet unknown microhabitat or more likely are so few in number that they remain virtually undetected.

There are fewer than 200 hellbenders recorded in Ohio. This is due in part to

their very secretive nature as well as to their low population density. Higher densities may have been common in Ohio before the land clearing and resulting siltation of streams by European settlers.

While the present study provides data on the Ohio distribution of hellbenders, little information exists about nests, eggs, larvae, population densities, and migration patterns within a stream. The Ohio Department of Natural Resources has recently revised its endangered species list. Ohio now joins Illinois, Indiana, and Maryland (Pisani 1976) in affording protection to the hellbender as an endangered species.

ACKNOWLEDGMENTS

I would like to thank Robert Jaeger, Raymond Semlitsch and two anonymous referees for their review of an earlier version of the manuscript and Fran Baran, Ken Latkovic, Joyce Murphy, and two anonymous referees for reviewing this version. For help in the field I would like to thank Linda Beebe, Tad Chrismiller, Bud DeWillie, Floyd Downs, Ken Fritz, Mike Greenlee, Chris Ingersol, Andy, Eric, Mike, Paul Jr., and Paul Johanni, Orion Johnson, Pete Joniak, Sam Leach, Rich Nielson, Paul Oswald, Erik, Joan and Laura Pfingsten, Al Reinke, Chris Reinke, Al Root, Dave Ross and Merrill Tawse. Financial support for this work was provided by the Ohio Department of Natural Resources with non-game wildlife tax checkoff funds.

REPRODUCTIVE DATA ON THE CHELID TURTLE *Chelodina siebenrocki* FROM NEW GUINEA

Chelodina siebenrocki Werner 1901 is a poorly-known snakeneck chelid turtle that occurs only in the southern coastal swamps of the island of New Guinea. It is most closely related to the northern Australian species *Chelodina rugosa* (Rhodin and Mittermeier 1976). The only information available on the morphology, natural history, and reproduction of *C. siebenrocki* is presented in Rhodin and Mittermeier (1976). They document the only recorded data on clutch and egg size for the species. Data were reported from two egg clutches, comprising 4 and 17 eggs, with egg size averaging 36.1 x 28.9 mm in the smaller clutch, and 35.0 x 28.3 mm in the larger clutch. Since then, we have observed four more egg clutches laid in captivity by two female *C. siebenrocki*. These observations were made in our respective collections of turtles kept in indoor facilities in northeastern United States (see Table 1 for summary).

One female (carapace length 255 mm, body mass 2.5 kg) from the vicinity of Daru, Western Province, Papua New Guinea laid a single clutch of 11 eggs (see Table 1 - Clutch 1). These eggs had an average mass of 20.5 ± 0.47 gm (mean ± S.D.). The 11 eggs were deposited over 19 days and were laid at the following intervals (day number:eggs laid): 1:2, 2:2, 5:1, 8:1, 10:1, 11:1, 15:2, 19:1. Egg-laying occurred in late June through early July 1977, after obtaining the specimen from the wild in April 1977. No hatchlings resulted.

A second female (carapace length 261 mm) from the vicinity of Merauke, Irian Jaya, Indonesian New Guinea laid three clutches of 16, 19, and 14 eggs respectively (see Table 1 - Clutches 2, 3, and 4). The clutch of 16 was laid in April 1988, 2 eggs hatched 6 months later in October after incubation at 29°C in damp vermiculite. The clutch of 19 was laid in April 1989, of which 2 eggs hatched 5 months later (measurements of one hatchling at age ca. 1 month with egg caruncle still present: carapace length 37.5 mm, width 27.0, depth 13.7, head width 11.3). The clutch of 14 was laid in September 1989, suggesting the potential of a two-clutch laying season, and 10 hatchlings resulted only 3 months later.

Egg sizes of the various species of *Chelodina* have not previously been compared, except for the work by Legler (1985) where he compares *C. "expansa"* (a generic grouping including *C. expansa, C. rugosa,* and *C. oblonga)* with *C. "longicollis"* (a generic grouping including *C. longicollis, C. novaeguineae,* and *C. steindachneri).* We have compared our data on egg length and width for *C. siebenrocki* with data from the literature for other species of *Chelodina* (Table 2 and Figure 1). Of note is that *C. siebenrocki* eggs fall at the upper end of the size spectrum, most similar in size to the other large species *C. expansa* and *C. rugosa.* Also of interest is the separate clustering of smaller eggs in the smaller species *C. longicollis* and *C. steindachneri.* The eggs of *C. parkeri* and *C. oblonga* are somewhat intermediate-sized between Legler's two "generic" groupings, with *C. parkeri* also being differentiated by having slightly more spherical eggs than all the other *Chelodina* species.

The Diet of *Amphisbaena darwinii heterozonata* in Argentina

Amphisbaena darwinii heterozonata has a wide distribution in Argentina (Gans 1966; Cei 1986). However, locating individuals is difficult because they are secretive. As a result, our knowledge of its biology is limited. Information about the diet of *A. d. heterozonata* found near Buenos Aires was published by Gallarde (1967, 1977). The present report describes stomach contents for a population from near the northwestern distributional limit of the subspecies.

Amphisbaenids were captured during two days (26 specimens between 1100 and 1500 h on 5 May 1983, and 27 between 0900 and 1100 h on 6 May 1983) by walking behind a caterpillar tractor that cleared a section of dry woodland at Finca San Javier, Anta Department, Salta province, Argentina (25° 05' S; 54° 10' W). The sampled area totaled one hectare. While dragging grass and shrubs the machine also removed a ground layer of about 15 cm thickness. This activity disturbed the habitat of snakes, lizards, and amphisbaenids that rapidly fled or were captured. All specimens were formalin-fixed in the field. Snout-vent lengths ranged between 110 and 212 mm ($\bar{X}$= 174.2 mm; SD = 28.52). Their size homogeneity prevented division into age-class intervals. Sexes were not discriminated.

Dietary analysis through dissection was based upon the 39 specimens whose digestive tracts were not mutilated by the tractor. Food items were classified to family level whenever possible. The number and frequency of each food category was estimated. Volumetric data were excluded because the fragmentation of ingested organisms prevented direct measurement.

Stomachs ranged from nearly empty in two specimens to a maximum of 47 termites in another. The quantity of matter present in the intestines was also quite variable, and usually mud-like. Isoptera and Coleoptera in the hind gut were recognizable by the presence of their undigested mandibles; however, a more complete analysis of the intestinal contents was not possible, as only chitinous, digestion-resistant parts remained. Stomachs and intestines of 30 specimens contained grains of sand.

The main component of the diet was termites (Isoptera), by number as well as frequency (Table 1). The worker and soldier castes jointly accounted for 92.7% of discrete elements consumed; one specimen had also eaten a physogastric queen from the colony. Thus, the presence in the diet of alternative components was very low, even including the vegetable matter.

Gallardo (1967, 1977) identified Hymenoptera (ants), Orthoptera, and Coleoptera adults, and larvae of Lepidoptera in the diet of Amphisbaena darwinii heterozonata. Accordingly, Cei (1986) assigned it to a mainly insectivorous regime. Studies of prey selectivity and foraging mode for this species are unknown. Its strong dentition, typical of all amphisbaenids, suggests that it could also prey upon small vertebrates. A larger sympatric species, *A. camura*, ate lizards and rats in the laboratory, tearing them (Gans 1966).

The diet of this sample of *A. d. heterozonata* showed low diversity. Insects were the only arthropods eaten, with a clear preponderance of termites. The plant materials ingested were assumed to be accidentally consumed, because they were fragments of withered leaves and twigs, without much nutritional value.

The consumption of diverse food items (the "generalist" condition) characterizes a wide range of lizards (e. g., Pianka 1986; Armas et al. 1987; Duellman 1987; Vega et al. 1988). Published accounts on *Amphisbaena* are thus far too scarce for accurate comparisons. Available data on the diet of *A. d. heterozonata* in two different and distant geographic regions (Gallardo 1977; this paper), however, suggest the strategy of a generalist-opportunist. The high preponderance of termites found in our sample seems related to the social habits of these insects, allowing for the consumption of many individuals when the colony is discovered, rather than a specialization by this species of amphisbaenid. The nature of the food items, as well as the sand and the type of plant parts ingested, suggest that food was obtained in underground galleries or in the sub-stratum, under leaf litter or logs.

CANNIBALISM IN TWO SPECIES OF ARBOREAL PITVIPER, *Trimeresurus wagleri* AND *Bothriechis schlegelii*

Arboreal pitvipers of the genera *Trimeresurus* and *Bothriechis* occur in tropical southeastern Asia and tropical America, respectively. Although these genera are geographically isolated, they appear to have evolved similar feeding strategies. These snakes are ambush predators that often strike in response to tactile input from potential prey. Cannibalism has not been reported in these species.

Trimeresurus wagleri is a small (ca. 0.5 m), heavy-bodied arboreal pitviper from the Malaysian Peninsula, Sarawak, Indonesia, and the Philippines (De Rooij 1917; Taylor 1922; Tweedie 1953). In captivity, this snake normally drapes itself over branches with the head positioned at midbody. The highly prehensile tail is usually coiled tightly around a branch, and the snake remains motionless. When the snake is touched posterior to the head on the side of the body, it will often strike in the direction of the stimulus. We presume that individuals act similarly in the wild. Known prey items of *T. wagleri* include birds, lizards, and mammals (De Rooij 1917; Loveridge 1946; Tweedie 1953). We have also observed this species eating frogs (*Hyla* sp.) in captivity. It has not been reported to eat snakes.

In March 1988, three juvenile *T. wagleri* were maintained together in a 46 x 31 x 32 cm glass aquarium furnished with branches. Water standing in the bottom of the aquarium provided humidity and the snakes were periodically misted with water. Snakes 1 (unknown sex) and 3 (female) were of ca. the same size while snake 2 (male) was slightly smaller. Snakes 1 and 2 were fed newborn laboratory mice (*Mus musculus*) ca. every three weeks. Snake 3 was introduced on 8 February 1988. On 18 March, snakes 1 and 2 were fed one newborn *M. musculus* each. Snake 3 refused food.

The snakes were in typical resting positions on the evening of 24 March. The following morning, snake 3 was missing and it was apparent from the size of snake 1 that it had consumed snake 3. That afternoon a radiograph of snake 1 indicated that snake 3 had been consumed tail first. Snake 1 regurgitated snake 3 on 26 March at 2145 h. Snake 1 was misted on 27 March inducing a large defecation. On 28 March, snake 1 was seen alive at 1245 h and was found dead at about 2100 h. The snake was measured at that time (SVL = 280 mm, TL = 36 mm).

Bothriechis schlegelii is a relatively slender prehensile-tailed pitviper ranging from northern Chiapas, Mexico, southward into Colombia, western Venezuela, and northwestern Ecuador (Campbell and Lamar 1989). This species is found in a variety of habitats, including tropical moist forest, wet subtropical forest, and montane wet forest (Campbell and Lamar 1989). It is predominantly an ambush predator; however, it may not be as sedentary as *T. wagleri*. Prey of this species includes birds, lizards, frogs, and mammals (Do Amaral 1927; Alvarez del Toro 1982).

On 14 May 1989, an adult male (SVL ca. 400 mm, TL ca. 120 mm) was introduced into a 46 x 31 x 32 cm glass aquarium occupied by an adult female (SVL ca. 475 mm, TL ca. 150 mm). On 17 May at 2300 h both animals were coiled together on a branch above the cage floor. The following afternoon at 1300 h, the female was noticed on the cage floor in a loose coil, and had obviously consumed the male. The remains were digested posteriorly, indicating that the male had been swallowed tail first. The female was still alive and healthy in October 1989.

In these cases of cannibalism, we hypothesize that the conspecific snakes were moving about the cages in the darkness. The prey contacted the predators laterally on the body posterior to the head and a feeding response was initiated, terminating in the consumption of the conspecific that initiated contact. Snakes were consumed tail first, which seems unusual (Greene 1976).

Many other arboreal snakes appear to use the same feeding strategy as *T. wagleri* and *B. schlegelii;* examples are members of the genera *Atheris*, *Corallus*, *Ophryacus*, and *Chondropython* (personal observations). This "tactile" ambush style of prey capture probably evolved independently in these different groups, as Greene (1979) concluded for several types of antipredator behaviors. Behavioral experimenta-

tion on the tactile-ambush feeding strategy is needed to test the degree of convergence among these various forms as well as to design captive habitats that minimize cannibalism.

MEETINGS OF THE INTERNATIONAL COMMISSION ON ZOOLOGICAL NOMENCLATURE

What will doubtless be recorded as the most momentous meeting in the history of the International Commission on Zoological Nomenclature (ICZN) took place 4-5 July 1990, at the International Congress of Systematic and Evolutionary Biology, held at the University of Maryland, USA. At these sessions the Commission developed a series of fundamental principles to be adopted for the preparation of the forthcoming 4th edition of the International Code of Zoological Nomenclature that will revolutionize both the theory and practice of zoological nomenclature. Significantly, these principles were first enunciated as the result of an all-day session of the Commission held on America's celebration of the anniversary of the signing of its Declaration of Independence, July 4. Like the statements in that document, these historic changes in the code promise to free systematic biology from the tyranny of the past and provide sound and comprehensive guidance for the future.

Members of the ICZN in attendance at these meetings all contributed to a series of exciting and productive exchanges of ideas that led to overwhelming support for the fundamental and revolutionary revisions in the code described below. They included: O. Kraus (FR Germany, President), H.G. Cogger (Australia, Vice-president), W.J. Bock (USA), J.D. Corliss (USA), D. Heppell (UK), P.T. Lehtinen (Finland), A. Minelli (Italy), C. Nielsen (Denmark), W.D.L. Ride (Australia), J.M. Savage (USA), R. Schuster (Australia), and F.C. Thompson (USA). Clearly the Commission undertook the new initiatives for code revision in response to the changing needs of the user community and the burgeoning requirements for stable biodiversity data bases. Their goal was to retain the most essential features of previous codes while designing a foundation for the nomenclature of the future.

Underlying all of the Commission actions were three primary principles. First, that, as emphasized in the Preamble to the present Code (3rd ed.), the overriding purpose of the Code is "to promote stability and universality." The Commission agreed that this goal is best achieved by adopting procedures that validate names in current use rather than through following strict priority. Second, as succinctly stated by both Linnaeus and Strickland (the promulgator of the first Code of Zoological Nomenclature), that the names given to organisms are simply symbols representing taxa that enhance communication about them and allow development of information bases regarding them. Consequently the Commission decided that matters relating to details of orthography, transliteration, strict adherence to the rules of Latin grammar, determinations of gender and spelling are secondary to establishing and maintaining a unique, distinctive and stable name for each valid taxon. Third, that the provisions of the Code must be simplified and designed to insure easy and automatic application of them by practicing systematists, with minimum need to petition the Commission for use of its Plenary Powers.

In the following paragraphs I will mention the most important proposals for change adopted during the Commission's deliberations, including a meeting open to all members of the zoological community on 5 July. These matters will be presented below in what I perceive to be their order of significance, not in the order in which they were considered. It should be noted that the Commission reaffirmed throughout these meetings that the Linnean classification system, its hierarchy of taxa and the binomial system of nomenclature are fundamental and irreducible bulwarks of the Code.

Without question the most significant and revolutionary changes adopted at these meetings were those that will severely constrain the strict application of priority by giving heaviest weight to the criterion of current usage as the determinant for establishing the validity of names. The first and interim step in this process will be the bringing together of materials in Articles 23c, 79 and 80 of the Code making it mandatory that senior synonyms that have not been used in the 50 years prior to the date of publication of their rediscovery are to be rejected and are not to be used to upset a long accepted name. No application to the Commission will be necessary (contrary to the present Code) to maintain current usage.

Much more important than this improvement, in what might be called the statute of limitations for the resurrection of old names,

is a sequence of decisions that the Commission believes will provide a stable and universal zoological nomenclature for the 21st century. The first of these involves the early establishment by the commission of a List of Available Generic Names in Zoology. The list would be developed substantially from Neave's *Nomenclator Zoologicus* and the *Zoological Record* with additions and corrections. At the time of publication (e.g. 1996) the dates in the list (regardless of any subsequent findings) would be the final determinants of priority. In addition and most importantly, only the generic names on this list would be available for use! Any other name, subsequently discovered or not, would not exist for nomenclatural purposes. Obviously new names proposed after 1996 would be available from their date of publication.

A second step in this process will be to ask the appropriate specialist committees (e.g. Nomenclature Committees of the International Congress of various taxonomic groups) to prepare lists of family-group, genus-group and species-group names in current usage. These might be based on up-dated versions of the lists of living mammals and amphibians prepared by the Association for Systematic Collections, for example. After appropriate consideration the Commission would certify such a list as an Official List of Names in Current Use (LNCU). Names not on this list would not be available and would not exist for nomenclatural purposes. Obviously new names proposed for taxa after the publication of the LNCU would become available from their date of publication. This procedure means that for a particular group there will be no necessity to search for any names published prior to the appearance of the LNCU thus completely freeing the systematist from the past, Essentially each LNCU will be a new (although mini-) *Systema Naturae* and will serve as the new starting point for nomenclature in that particular major group. In poorly known groups it may be sometime before LNCU's will be prepared. For these taxa the revised Article 23c and the List of Available Generic Names in Zoology will provide maximum stability until LNCU's are available.

In another significant area the Commission recognized the inherent incongruity between the absence of knowledge of classical languages by most practicing systematists and the requirements of the Code. It was agreed that scientific names are only symbols for taxa in themselves carrying no special meaning and under the current Code may even be arbitrary combinations of letters. Consequently, while the Commission believes that names for taxa should continue to be based primarily on words of Latin and Greek derivation, the pertinent articles on name formation in the Code will be re-written without reference to the rules of Latin grammar. Specifically a simple and uniform method will be devised for forming family-group names for the future. The accepted spellings of older family-group names will be established by current usage, not Latin grammar!

Two other specific issues in the area of grammar were considered. It was agreed that in the case of species-group patronyms that terminate in *-ii* or *-i*, either spelling would be admissable regardless of the original spelling (e.g. *petersii* or *petersi*; *boylii* or *boyli*). Less clearly resolved was the matter of agreement in gender between generic and species-group names based on adjectives. The idea that generic names should be without gender received considerable support, however, there was no agreement on how to establish fixed spellings for the adjective-based species-group names. One alternative might be to make all generic names feminine for purposes of zoological nomenclature. Certainly it would be best if all members of a particular genus had the same adjectival terminations.

The areas of what constitutes publication and the criteria of availability were revisited. Clearly with development of new methods of electronic publication and printing, unintentional, accidental, personal or even mischievous proposals of new names for taxa are possible. The Commission favored the notion that to be published for purposes of zoological nomenclature a new name must appear in one of a substantial number of approved scientific journals or in books from an extensive list of publishers that were registered with the ICZN. Logistics for such a plan are complex and need further investigation but the aim is to insure publication in the primary scientific literature as opposed to privately printed and/or unedited sources. In the area of availability it is proposed that in order to be available (after a certain date) a new name must be accompanied by an abstract and/or diagnosis purporting to distinguish it from other similar taxa in a language using Latin letters, preferably "a language of the Code," language of the Code being any language so designated in the Code. Candidate languages are to be determined at a later date.

The Commission agreed that provisions should be added to the Code so that in cases where a type genus of a family-group name has been misidentified the first available name for the same taxon is to become the type genus and similarly a misidentified type species of a genus-group name should be replaced by the first available name for the same taxon. Another change would require all future species-group descriptions to include a designation of a holotype, syntypes or hapantotype or in certain cases of ephemeral organisms, an illustration that may be composite (some special designation will be required for these). Such types must be deposited in a museum or similar institution. After a stated date no new species-group name would be available if it does not meet these requirements.

Although the Code does not treat names of order-, class- or phyla-groups the commission is often thought to have authority in this area. There seems to be some advantage to the community if the ICZN could provide a list of such names in current use, with some indication of preference in usage. Consequently the ICZN will undertake the preparation of a list of recommended names in these categories in zoology. Hopefully this will encourage universality of usage of order-, class- and phyla-group names as key words, in titles and in abstracts.

An editorial committee chaired by F. Christian Thompson is in the process of drafting these dramatic changes into definitive form for action at the meetings of the International Union of Biological Sciences at Amsterdam, the Netherlands, in September 1991. It is important that systematists voice their support of these changes, which are based upon the Commission's response to the demands of both taxonomists and other members of the biodiversity community. Your comments may be directed to the Executive-Secretary, International Commission on Zoological Nomenclature, c/o Museum of Natural History, Cromwell Road, London SW 7 5BD, Great Britain. It is vital to the welfare and future of systematic biology that the progressive and exciting innovations in zoological nomenclature developed by the ICZN at Maryland become implemented. Your individual aid, through endorsement of the major principles described above, in bringing this great enterprise to fruition for the benefit of biologists and biology generally, is an essential ingredient in adoption of a Code of Zoological Nomenclature that emphasizes stability based on current usage and is designed for the needs of systematists in the 21st century.

I will conclude by noting specific actions by the Commission. Of particular interest to readers of this journal is the case of the three herpetological works on Australian and New Zealand taxa by Wells and Wellington (Case 2531). It was decided that each of the three titles would be considered individually. In addition before any further action is to be taken on these cases the Commission will seek the advice of the Nomenclature Committee of the World Congress of Herpetology for their opinion as to whether or not any or all of the three works in question pose a threat to the stability or universality of scientific nomenclature for the amphibians and reptiles of Australia and/or New Zealand. Of course until the Commission makes a final decision on this matter the nomenclature (existing usage) utilized prior to the Wells and Wellington publications should be followed.

RECENT POPULATION CHANGES

RECENT POPULATION CHANGES provides an outlet for anecdotal or minimally documented information on local extinctions or regional population changes. These reports could be valuable historic indications that might enhance our understanding of very long term population trends (in excess of 20 years) and changes in distribution patterns.

Manuscripts should be submitted directly to the editor of this subsection: Ralph W. Axtell, Department of Biological Sciences, Southern Illinois University, Edwardsville, IL 62026, USA.

POPULATION STATUS OF *Bufo exsul* MYERS, 1942

Recent reports have raised concern that anuran populations may be in decline on a world-wide basis (Barinaga 1990). The black toad, *Bufo exsul*, an endangered taxon of the *Bufo boreas* complex, is restricted to Deep Springs Valley, Inyo County, California. This toad is found only in a small area watered by the run-off from springs in an isolated valley of the Great Basin Desert in eastern California (Schuierer 1962, 1963).

In order to carry out a brief, informal survey of its present population status, we visited the population at Corral Springs and Buckhorn Springs in the southeastern part of the valley. Small populations at Antelope Springs, 5 mi to the northwest (Schuierer 1962) and at Bog Mound Springs north of Deep Springs Lake (Sherman 1980) were not visited. Our visit, 12-14 April 1990, coincided with the breeding period for this species, which extends from about mid-March to late April. One of us (FWS) has studied this population since 1952, and we have visited the valley sporadically over the intervening years.

Subjective population estimates were made during most occasions and the numbers seen during springtime visits have appeared fairly constant. More accurate counts and population assessments were attempted by Schuierer (1962, 1972) and Sherman (1980). These estimates range from more than 10,000 individuals for Corral Springs plus Buckhorn Springs (Schuierer 1962) to more than 22,000 for Corral Springs (1980).

During our most recent visit, all size classes (<1 yr; <2 yrs; 2-3+ yrs) of toads were seen in all suitable habitats. Adult toads prefer habitats with short plant cover and unobstructed access to still or slowly flowing water. Breeding sites are easily entered shallow waters with sufficient plant cover that protect eggs and tadpoles. Only three freshly deposited egg masses were observed, but small tadpoles (stages 25-27) were found more widely dispersed in shallow, slowly moving or standing open water. No gravid females or amplexing pairs were encountered, although release/encounter "chuckles" were occasionally heard.

During a ten-hour perambulation over the entire springs area, we encountered at least 700 toads. A small number were collected, measured from snout to vent, and released. Males and females in the largest age-class (3 yrs +) were present in equal numbers and measured 45-57 mm ($\bar{X}$=48.6 mm), males 45-52 mm ($\bar{X}$=48.6 mm). These measurements correspond with measurements for adults seen in previous years (Schuierer 1962), but are significantly less than adult sizes reported by Sherman (1980) for the same area: males 49 - 76 mm, $\bar{X}$=60.4 mm in 1977, 64.2 mm 1978; females 52 - 75 mm, $\bar{X}$=62.0 in 1977, 64.4 in 1978.

The numbers and sizes of animals appeared similar to those of our past visits, made over a 38-year span. In our estimation, there have been no major changes in the population size of *Bufo exsul* over this period. We plan to continue monitoring this population, and with time and funds permitting, to complete a more accurate analysis of this toad's population size and structure.

If this unique population is to survive, care must be taken that this small and restricted biotope is not changed in ways that make it less suitable for toads. We noted considerable land-moving activity within one km of Corral Springs; also a large waterfowl pond (ca. four acres in extent) has been developed in a former toad-breeding area between the springs' sloughs and the alkaline Deep Springs Lake that occupies the southern end of the valley. Happily eggs and tadpoles have now been found on the shallow south side of this pond.

LIFE HISTORY NOTES

See Herp. Review *21(1) for author's instructions.*

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). **Size Maxima**. On 16 October 1989 at ca. 2200 h, a record size *Ambystoma opacum* was collected during a rain shower on a paved road at the town of Makanda, Jackson Co., Illinois (T.10S., R.1W., Sec. 27, NW1/4). The specimen as measured alive (chlorotone anesthetized) was: SVL = 78 mm; TL = 136 mm. This specimen thus surpasses Conant's (1975. A Field Guide to the Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Company, Boston. 429 pp.) species size maxima (TL = 127 mm) by 9 mm. Smith's (1961. The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28(1), 298 pp.) Illinois record *A. opacum* (TL = 121 mm) was surpassed by 15 mm. The specimen was deposited in the Herpetology Collection, Southern Illinois University at Carbondale (SIUC H-3815).

Submitted by **MICHAEL REDMER**, 21 W. 103 Par Ln., Itasca, IL 60143, and **NICHOLAS J. TWESTEN**, 217 N. Meridian Rd., Glen Carbon, IL 62034, USA ●

ANURA

BUFO COGNATUS (Great Plains Toad). **Microhabitat Selection**. On 15 July 1989 between 2100 and 2135 h, I observed several (ca. 18-24) adult *Bufo cognatus* along a short distance of the west shore of the San Luis Lake (Alamosa Co., Colorado, ca. 2300 m elevation). A stiff wind was blowing from the east, forming a line of foam where the waves lapped the shoreline. The air temperature was 21° C, the water temperature 17° C, and the foam temperature 19.2° C (all temperatures measured with a Schulteis reptile thermometer). Most toads were first observed within the foam along the shoreline; all were found within the foam or on the land within a short distance of the water and foam (maximum observed distance was 30 cm), although some toads retreated into the water when disturbed. No calling was observed during the period of direct observation or later while we camped nearby.

Table 1 shows the locations and body temperatures of five of the toads. Duellman and Trueb (1986. Biology of Amphibians. McGraw-Hill Book Co., p. 216) suggest that in nocturnal amphibians, "regulation of body temperature, if it occurs at all, is restricted to those times when the animal is in its diurnal retreat." As moving air causes greater water loss through amphibian skin, selective utilization of the shoreline foam by the toads probably occurred because the foam provided a comparatively favorable microhabitat both in terms of water economy and possibly of temperature. I thank my son, Todd Wilcox, who assisted with these observations.

Table 1. Body temperatures and locations of *Bufo cognatus*.

Land	Water	Foam
19.4° C	17.0° C	18.8° C
16.8° C		17.8° C

How to Dress Like a Herper

The Gray Treefrog, calling on a warm spring night, is printed in color on a black T-shirt. Artwork by Karl Johnson

The Wood Turtle, foraging in a patch of ferns, is printed in color on an ecru (off-white) shirt. Artwork by Sarina Brewer

These shirts will be made available for a limited time at a price of $12 each, or both for only $22. Sizes are Small, Medium, Large and Extra Large.

OSTEOCEPHALUS TAURINUS (Treefrog). **Predation.** Few species of birds of the family Cuculidae are known to feed on frogs, and only two records are for Neotropical cuculids: *Guira guira* (Schubart et al. 1965. Arq. Zool. Sec. Est. S. Paulo 12:95-249) and *Crotophaga ani* (Sick 1985. Ornitologia Brasileira Vol. 1, Ed. Univ. Brasília, Brasília. pp. 315-322). In neither case was the frog identified. In November, 1988 at Anavilhanas Archipelago, 100 km NW of Manaus on the Rio Negro, Brasil, we observed a Squirrel Cuckoo (*Piaya cayana*) capturing an *Osteocephalus taurinus* (10 cm TL). After capture the cuckoo flew to the ground with the frog held in its bill. Twice the frog escaped by jumping ca. 20 cm from the bird, and each time it was recaptured. The cuckoo held the frog by its head and beat it on the ground several times, and then beat it on a log. The cuckoo attempted to dismember the frog, but was unsuccessful. It then perched at a height of 1.5 m without the frog. The dead frog was subsequently found amongst the leaf litter under the perch, and we conclude that it was probably abandoned because it was too large. This observation suggests that the Squirrel Cuckoo may be an important predator of smaller tree frogs.

RANA PALUSTRIS (Pickerel Frog). **Predation.** Most accounts of *Rana palustris* make reference to its toxic skin secretions, even though the exact components of the toxins and the extent of their effects on would-be predators remain poorly known. Wright and Wright (1949. Handbook of Frogs and Toads of the United States and Canada. Comstock, Ithaca, NY. xii + 640 pp.) report the secretions as being irritating to dogs and fatal to other frogs placed in the same container. Dunn (1935. Copeia 1935(2):85-98.) and others have offered these frogs to captive snakes, nearly always with negative responses. However, few if any instances of natural predation have been reported.

Two adult *Rana palustris* were removed from the stomach of an adult male mink (*Mustela vison*) collected along the Broad River, between 6.8 and 9.2 km SW Rutherfordton, Rutherford Co., North Carolina in November, 1988. This appears to be the first record of natural predation on this frog known from North Carolina. The fact that the mink was a mature animal and had almost certainly encountered *R. palustris* before, and the fact that it ate (apparently in their entirety) not only one, but a second frog, suggests that the skin toxins of *Rana palustris* may be ineffective against minks.

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, P.O. Box 27647, Raleigh, NC 27611, USA ●

RANA SYLVATICA (Wood Frog). **Reproductive Mortality.** Wood frogs are explosive breeders, completing most of their reproductive activity in less than a week. Male-male competition for mates can be quite intense, with as many as ten males grasping and attempting to amplex with a single female (Phillips, pers. obs.; Berven 1981. Evolution 35:701). On 14 March 1990 an unusual cost of reproduction for female *R. sylvatica* was observed when two females were found that appeared to have been crushed to death by males. One female was found in a "mating-ball" of five males. Upon collection, the female was dead, with its tongue and other visceral parts protruding from its mouth. The other female was observed in amplexus with a single male. This female was also dead, with its intestine protruding from a hole in its side. These observations were taken at a small (10 m diam, 0.5 m deep), ephemeral pond located in the Indiana Dunes National Park, Porter Co., Indiana.

This is the first female mortality of its kind observed at this site in three years (collection of more than twenty mating-balls). The difference this year may be due to the much higher temperature (23° C) on that day, which was more than 10° C warmer than the average temperature during the mating season. Males are visibly more active on warm days, and may have simply overwhelmed these females on this very warm day.

CROCODILIA

ALLIGATOR MISSISSIPPIENSIS (American Alligator). **Diet.** Incidental to our studies on Florida manatees, we observed alligators at the Merritt Island National Wildlife Refuge, Brevard Co, Florida, feeding on horseshoe crabs (*Limulus polyphemus*) on four occasions from 1987 through 1989. We estimated that the alligators were 2.5 - 3.5 m long and the horseshoe crabs 30 - 50 cm long. All observations occurred in the brackish, turbid waters of Banana Creek near State Highway 3. On one occasion we photographed a 2.5 m alligator moving 20 m to a horseshoe crab swimming upside down at the surface. The alligator grasped the crab in its mouth and returned to shallow water where it consumed the crab above water within about 4 min. In a recent review, Wolfe, Bradshaw, and Chabreck (1987. Northeast Gulf Sci. 9(1):1-8) noted a number of crabs, shrimp, and crayfish among a diverse array of alligator food items, but they did not list *Limulus*. The taking of horseshoe crabs by alligators appears to have been overlooked, and our observations suggest that horseshoe crabs may constitute an important component of the alligator's diet in certain coastal regions of Florida. Photographs documenting this feeding behavior have been placed on file at the Florida Museum of Natural History, Gainesville, Florida.

Submitted by **JAMES P. REID** and **ROBERT K. BONDE**, U.S. Fish and Wildlife Service, 412 N.E. 16th Avenue, Rm. 250, Gainesville, FL 32601, USA ●

ALLIGATOR MISSISSIPPIENSIS (American Alligator). **Behavior.** A tail wagging sequence that appeared to be related to feeding was observed in several adult alligators during spring 1988 at Brazos Bend State Park, Fort Bend Co., Texas, and in one individual in April, 1990 at Paynes Prairie State Preserve, Alachua Co., Florida. The alligators were in marshy, somewhat stagnant bodies of water with little or no current and varying water depths of 0.3 - 1.0 m. The posterior third of the tail rapidly swept through the water and mud in a 180° arc. Simultaneously, the head was moved from side to side in a 90° arc with the mouth held partially open. Occasionally the alligator would lunge at the turbid water and appear to swallow as if feeding. We noted little variation amongst alligators displaying this behavior.

The tail wagging greatly increased the turbidity of the water. We speculate that it made oxygen utilization extremely difficult except near the surface for potential prey such as amphibians, fish, and invertebrates, as well as physically dislodging them, thus increasing capture success by the alligator.

Submitted by **DENNIS JONES**, Brazos Bend State Park, 21901 FM 762, Needville, TX 77461, and **LOUISE HAYES-ODUM**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, TX 77843, USA ●

TESTUDINES

CARETTA CARETTA (Loggerhead Sea Turtle). **Habitat.** On 1 October 1989, we identified a post-hatchling loggerhead (10-12 cm CL) captured at an artificial reef in the Gulf of Mexico, 15 km S of Pensacola, Florida (30°12'N, 87°14'W). The turtle may have followed a scuba diver to the surface from the 37 m deep reef, where it was repeatedly attacked, but not injured, by two sea gulls (*Larus atricilla*?) before its "rescue" (J. Ferguson, pers. comm.). We were unable to measure or weigh the animal, which was quickly released by the Florida Marine Patrol in Pensacola Pass (H. Gomez, pers. comm.). We found no evidence of tags or tag scars on the animal.

The usual habitat of post-hatchling loggerheads is in offshore oceanic waters (see Carr 1987. Conserv. Biol. 36(2):92-100). This is apparently the first report of a non-stranded, non-sargassum-associated post-hatchling in nearshore waters, and the first record of an "oceanic-stage" turtle associated with an artificial reef in the Gulf of Mexico. It is likely that this turtle was prematurely advected into coastal waters, and unlikely that it will survive seasonally cold water temperatures that occur in the northern Gulf.

In our opinion, post-hatchlings stranded or accidentally captured during late fall or winter in the northern Gulf of Mexico should be released offshore in or near boundary currents, such as the Gulf of Mexico Loop Current or its eddies, or held captive in appropriate facilities until juveniles (>20 cm CL) or the return of favorable surface water temperatures in March-April.

We thank N. Mrosovsky for editing a draft of the manuscript. Our thanks to G. Ferguson, and the Florida Marine Patrol for furnishing capture and release information.

EMYDOIDEA BLANDINGI (Blanding's Turtle). **Parasites.** On 28 July 1988, an *Emydoidea blandingi* was collected by hand, at the southeast end of Big Clear Lake, Arden, Frontenac Co., Ontario. This specimen had a CL of 143.65 mm, a CW of 107.55 mm, and was host to seven leeches. The leeches were deposited at the National Museum of Canada (NMC). Three of the leeches were *Placobdella parasitica* (NMC A 1989-0009), a commonly encountered turtle leech. The remaining four leeches were *Placobdella ornata* (NMC A 1989-0008). This is believed to be the first confirmed report of parasitic interaction between *P. ornata* and *E. blandingi*.

The capture site was a wide, shallow, and densely vegetated stream that flowed into the lake. The bottom substrate consisted of several feet of detritus. The air temperature was 32° C, and the water temperature was 31° C at 50 mm at time of capture. The turtle was released as part of a mark-recapture study.

I thank Jaqueline Madill, Assistant Curator, Vermes Section (NMC), for identifying the leeches.

GRAPTEMYS VERSA (Texas Map Turtle). **Size Maximum and Diet.** McKinney (1987. Herp. Review 18(1):17) reported a maximum size of 171 mm CL for *Graptemys versa* and listed measurements for eight specimens all greater than the 127 mm CL reported by Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 2nd ed. Houghton Mifflin Co., Boston. 429 pp.). Vogt (1981. Cat. Amer. Amphib. Rept. 280.1-280.2), however, previously had reported a maximum size of 183 mm CL.

On 3 July 1984 we collected a female *Graptemys versa* (TCWC 62676) in the San Saba River at the Schleicher-Menard county line, Texas, larger than any previously published record. From this turtle the following straight-line measurements were recorded: carapace length = 214 mm; carapace width = 154 mm; plastron length = 188 mm; plastron width = 125 mm; head length = 67 mm; head width = 40 mm. Head measurements are reported because this individual exhibits megacephaly, possibly associated with a diet of gastropods, shells of which were present in feces. This is the first report of diet for wild individuals of this species. The project for which this specimen was collected was funded by the Texas Agricultural Extension Station.

MALACOCHERSUS TORNIERI (Pancake Tortoise). **BEHAVIOR.** The power used in the righting movements of pleurodiran and most cryptodiran chelonians is transmitted by the head and neck. None of the testudinines with a convex carapace can right themselves without the head touching the substrate. *Malacochersus tornieri* differs from most testudinines in that it has the least convex carapace; this species can right itself without using the head. It also differs from other chelonians in that the power for righting activity is transmitted by the forelimb. This behavior was observed in eight specimens imported from Tanzania. It is speculated that *Malacochersus* was derived from ancestral testudinines which possessed a convex carapace, and the ability to right using the forelimb is a secondarily derived characteristic.

SAURIA

LEIOCEPHALUS SEMILINEATUS (NCN). **Parasitism.** Greve and Powell (1989. J. Parasitol. 75:677-679) and Powell et al. (1990. J. Helminthol. Soc. Washington 57:75-77) described the nematode parasite *Skrjabinoptera leiocephalorum* (Spirurida: Physalopteridae) and discussed its occurrence in *Leiocephalus schreibersi* and *L. barahonensis* from Hispaniola. Stomachs of sympatric lizards, including *L. semilineatus*, were also

examined, but no nematodes were found. In the course of subsequent investigations into the food habits of Hispaniolan *Leiocephalus*, we have found an occurrence of *S. leiocephalorum* in *L. semilineatus*. This represents a new host record.

A female *L. semilineatus* (SVL 44 mm), collected along the Río Tábara near Highway 44 (130 m elev.), Provincia de Azua, República Dominica on 20 May 1989, was found to be infected with 4 physalopterid nematodes subsequently identified as *S. leiocephalorum*. The collecting site represents a new locality record for the parasite. Three nonoviferous females (4.77-5.19 mm) and one male (5.19 mm) were found free in the stomach lumen, admixed with ingesta. This was the only one of 53 *L. semilineatus* found to be infected. The lizard is on deposit in the Bobby Witcher Memorial Collection (BWMC 04010) at Avila College. Nematodes are in the parasitological collection at Avila College (no numbers assigned).

We wish to thank Jaime Villa, Scott A. Maxey, S. Scott Duer, and Kimberly L. Jurd for their assistance in the field and lab. José A. Ottenwalder of the Parque Zoológico Nacional facilitated opportunities for field work. Permits were graciously provided by Emilio A. Bautista M., Director, Departamento de Vida Silvestre, República Dominica.

SCELOPORUS JARROVI (Mountain Spiny Lizard). **Behavior**. Sexual interference refers to behavior in which an animal (usually a male) decreases the fitness of a conspecific without increasing its own fitness by preventing the conspecific from mating. Numerous examples of this are known from a variety of taxa (Alcock 1984. Animal Behavior: An Evolutionary Approach. 3rd ed. Sinauer Assoc., Sunderland, MA. Pp. 376-378). On 17 September 1989 sexual interference was observed in *S. jarrovi* in a high elevation (2600 m) population in the Chiricahua Mountains, Cochise Co., Arizona. This observation was made during a focal sampling period (1346 - 1416 h) of a large male *S. jarrovi* (93 mm SVL, 37 g mass) made as part of an ongoing study of the population.

The lizard was observed to move about its home range displaying for a period of 1 min, then rapidly move a distance of 10 m to a point well outside of its home range where it had never been observed previously and then (1356 h) physically attack a pair of lizards that I had not observed until that time. The pair consisted of another large male (89 mm SVL, 29 g mass) and a small unidentified female who appeared to have been involved in courtship. The period of physical contact was less than one second. After the initial attack the first male remained within 5 cm of the pair. The second male maintained his grip on the neck of the female for roughly five seconds and then released her. The female rapidly left the area and was not resighted. The two males remained motionless and adjacent to one another for a period of three minutes. During this time both males laterally compressed their bodies and held them high off the ground but did not display. At 1359 h the first (attacking) male moved off about 1 m and then moved an additional 5 m at 1401 h and temporarily moved out of sight. At 1402 h the first male had returned to his own home range and resumed an activity pattern of basking alternating with periods of display. The second male started displaying periodically after the first male moved away but did not pursue him.

UTA STANSBURIANA (Side-blotched Lizard). **Cannibalism**. Intra-species predation is a more widespread and consequential phenomenon than is usually recognized (Polis 1981. Ann. Rev. Ecol. Syst. 12:225-251). Among lizards for example, the consumption of juveniles by adult individuals may be a fairly common occurrence (see Hews 1989. Herp. Review 20(3):71; Polis and Myers 1985. J. Herpetol. 19:99-107; and included references).

In the course of removing the digestive tracts of ca. 600 adult *U. stansburiana*, I found the remains of juvenile *Uta* in the stomachs of three individuals. The actual incidence of cannibalism was undoubtedly higher than indicated by this sample, because only around half of these lizards were collected when hatchlings were present, and I only opened stomachs when a suspect prey item was visible through the stomach lining.

On 28 June 1987 I collected an adult male *U. stansburiana* (46 mm SVL) in Inyo Co., California, whose stomach contained a juvenile male Uta (ca. 25-30 mm SVL). On 23 July 1987 I collected two adult males (48 and 49 mm SVL) in Grant Co., Washington, both of which contained the partially digested remains of juvenile *Uta*.

In two previous reports of cannibalism in this genus for which the sex of the cannibal was noted, adult males were also the perpetrators (Hews op. cit.; B. Sinervo, pers. comm.). Taken together, these observations indicate that cannibalism is significantly more common by males than by females ($P = 0.031$, $N = 5$, one-tailed binomial test). The reason for this apparent sexual difference in the frequency of cannibalism is presently unknown, but could be related to the larger size of males, or to a suppression of cannibalism among females whose home ranges would likely overlap those of their offspring (see Tinkle 1967. Misc. Publ. 132, Mus. Zool., Univ. Michigan). It would be instructive to examine other reports of cannibalism in sceloporine lizards to determine whether this pattern is typical of the group. I also encourage other workers to report the sex of cannibals in future communications.

Although I overlooked many potential instances of cannibalism (see above), evidence suggests that intra-specific predation may have been fairly common, at least in the Grant Co., Washington population. Specifically, 2 of the 12 large males (>47 mm SVL) collected on 23 July 1987 contained conspicuous, undigested remains of juvenile *Uta*. Therefore, at least 17% of the large males in this population had fed recently on juvenile lizards. Because *U. stansburiana* is the only lizard that occurs on this site, this observation lends support to the notion that an absence of competitors may facilitate the expression or evolution of cannibalism (Polis op. cit.).

A variety of benefits might accrue to cannibalistic individuals. The instances of cannibalism reported here however, were probably manifestations of normal foraging behavior (Polis and Myers 1985. J. Herpetol. 19:99-107). Indeed, the summer period (when these samples were collected) is a time of peak *Uta* abundance (primarily hatchlings) and potentially low resource levels; hence, this is the time when conditions might favor cannibalism as an alternate means of energy acquisition (see Polis op. cit.).

I thank Landin Boring for help collecting

lizards, Raymond B. Huey for comments which improved the manuscript, and Bill Fulleton for allowing me to study *Uta* on his property near Vantage, Washington.

Submitted by **BYRON S. WILSON**, Department of Zoology, NJ-15, University of Washington, Seattle, WA 98195, USA ●

WETMORENA HAITIANA (NCN). **Food Habits**. *Wetmorena haitiana* is a semi-fossorial anguid whose range is restricted to the Massif de la Selle and the Sierra de Baoruco on Hispaniola (Schwartz 1965. Proc. Biol. Soc. Washington 78:39-48; Schwartz and Henderson 1984. Milwaukee Publ. Mus. Spec. Publ. Biol. Geol. No. 4:1-70).

Twenty-seven *W. haitiana* (M:F 12:15; SVL 33-95 mm, $\bar{X}$ = 68.4 + 17.6 mm) were taken from two localities in the Sierra de Baoruco, República Dominica in March, 1986, 1988, and 1990. Collection sites were in mesic upland forest 47 km N Cabo Rojo, Pedernales Province, elev. ca. 1000 m, and near Monteanada Nueva, 12 km S Cabral, elev. >1100 m. Stomach contents were analyzed and arthropods identified to order. Volumes of food items were determined using methods of Milstead (1957. Texas J. Sci. 9:410-447).

Thirty-eight prey items representing 3 phyla, 5 classes, and 10 orders were identified. In addition, shed lizard skin was found in one animal, grit in another, and plant materials in six specimens. Ingestion of grit and plant material is assumed to have been adventitious. Relative numbers, volumes, and frequencies of occurrence for all food items are presented in Fig. 1. Sample sizes were too small to determine if food habits varied by sex. There was no correlation between SVL of lizards and the volume of prey items consumed (r = 0.37, N = 22, P = 0.05). Specimens were deposited in the Bobby Witcher Memorial Collection at Avila College (BWMC 02739-02740, 03390-03400, 04236-04249).

Few data dealing with food habits of neotropical anguid lizards have been reported. Incháustequi et al. (1985. Amph.-Rept. 6:195-201) and Vitt (1985. Paps. Avulsos Zool. Mus. Zool. Univ. S. Paulo 36:69-76) characterized gut contents of *Diploglossus warreni* from Hispaniola and *D. lessonae* from northeast Brazil, respectively, as being indicative of opportunistic foraging. *W. haitiana* appears to be similarly willing to feed on any food item it encounters.

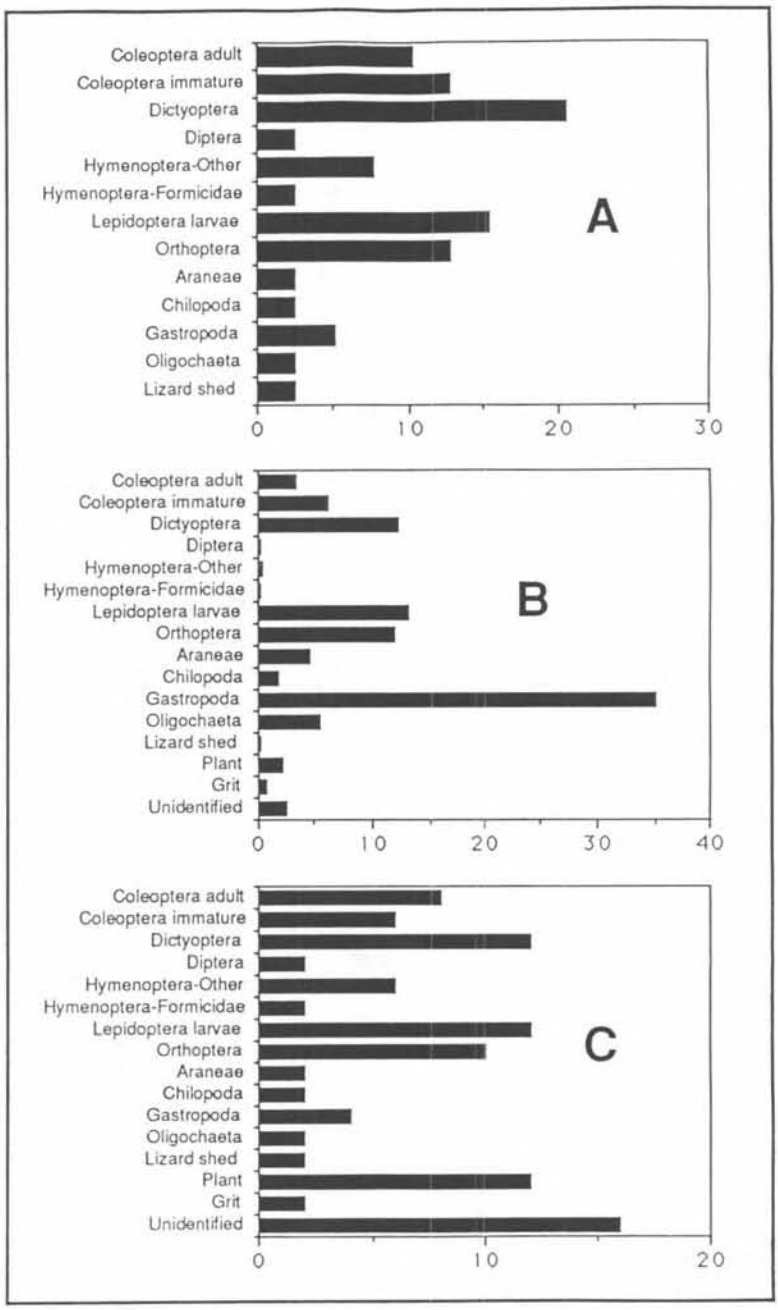

Figure 1. Relative numbers (A), volumes (B), and frequencies of occurrence (C) (expressed as percentages) of stomach contents in *Wetmorena haitiana*.

We wish to thank Donald D. Smith, John S. Parmalee, Jr., Denise Rector, and members of the Avila College Field Biology Classes of 1986, 1988, and 1990 for their assistance in the field and lab. José A. Ottenwalder of the Parque Zoológico Nacional facilitated opportunities for field work. Permits were graciously provided by Emilio A. Bautista M., Director, Departamento de Vida Silvestre, República Dominica.

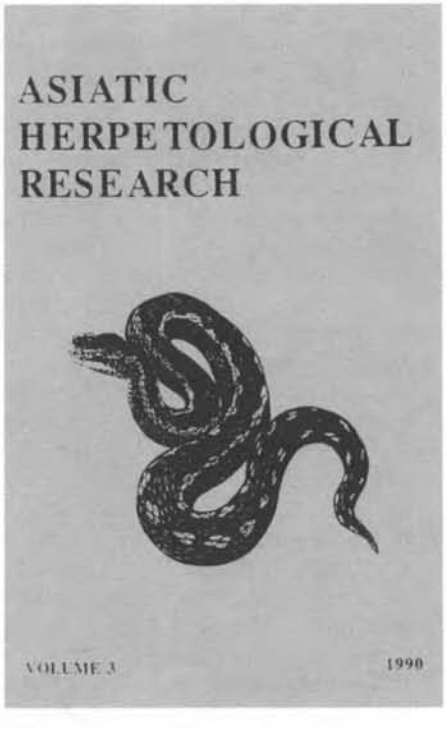
ASIATIC HERPETOLOGICAL RESEARCH

(formerly *Chinese Herpetological Research*)

Asiatic Herpetological Research is a new journal concerning, but not limited to, Asian herpetology. It is published by the Chinese Society for the Study of Amphibians and Reptiles, headquartered in Chengdu, China, and the Asiatic Herpetological Research Society at the Museum of Vertebrate Zoology, University of California.



The journal is edited by an internationally-recognized group of experts on amphibians and reptiles:

Editor: Ermi Zhao (China–Beijing).
Managing Editors: Kellar Autumn, J. Robert Macey, and Theodore J. Papenfuss (all USA).
Editorial Board: Kraig Adler (USA), Natalia B. Ananjeva (USSR), Leo Borkin (USSR), Bihui Chen (China–Beijing), Yuanchong Chen (China–Beijing), Ilya S. Darevsky (USSR), Indraneil Das (India), William E. Duellman (USA), Hajime Fukada (Japan), Meihua Huang (China–Beijing), Carl Gans (USA), David M. Green (Canada), Robert F. Inger (USA), Kuangyang Lue (China Taipei), Hidetoshi Ota (Japan), Anming Tan (China–Beijing), and Datong Yang (China–Beijing).

THE JOURNAL

The format of the journal is 8.5 x 11 inches (21.5 x 28 cm). *All articles are in English.* There are many photographs, figures, and maps, plus occasional color plates. The following titles from recent issues are representative of journal coverage:

"Defensive Behavior and Feeding Biology of the Asian Mock Viper, *Psammodynastes pulverulentus* (Colubridae), a Specialized Predator on Scincid Lizards," by Harry W. Greene (USA).
"Captive Reproduction of Chinese Alligators," by Zhengdong Zhang (China–Beijing).
"A New Species of the Genus *Paramesotriton* (Amphibia: Caudata) from Guangxi and a Comparison with *P. guangxiensis*," by Yetang Wen (China–Beijing).
"Species in the *Vipera kaznakowi* Complex in the Caucasus: Present Distribution, Possible Genesis, and Phylogeny," by Nikolai L. Orlov and Boris S. Tuniev (both USSR).
"Studies on Hynobiid Salamanders, With Description of a New Genus," by Kraig Adler (USA) and Ermi Zhao (China–Beijing).
"Thermal Sensitivity of Sprinting and Clinging Performance in the Tokay Gecko (*Gekko gecko*)," by Jonathan B. Losos (USA).
"Interim Report on the Freshwater Turtle Trade in Bangladesh," by S. M. A. Rashid (Bangladesh) and Ian R. Swingland (UK).
"Reptiles of the Democratic People's Republic of Korea. Part I. Serpentes," by Zbigniew Szyndlar (Poland) and Dam O. Hung (North Korea).
"A New Species of *Varanus* from Yunnan, With Comparison Between It and Six Other Species from Southeast Asia," by Datong Yang and Simin Li (both China–Beijing).
"Karyotypes of Some Species of *Bungarus*," by Michihisa Toriba (Japan).
"Intergradation Between *Melanochelys trijuga trijuga* and *M. t. coronata* (Testudines)," by Indraneil Das (India) and Peter C. H. Pritchard (USA).
"Mating Call Structure of the Chinese Frog, *Rana nigromaculata*," by Yong Mu and Ermi Zhao (both China–Beijing).
"Studies on the Early Embryonic Development of *Rana rugulosa* Wiegmann," by Jionghua Pan and Danyu Liang (both China–Beijing).

MANUSCRIPTS

Manuscripts for publication are solicited and should be addressed to Asiatic Herpetological Research Society, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA. Detailed instructions are published at the end of volume 3 (1990).

MEMBERSHIP AND SUBSCRIPTIONS

Individual memberships in the USA are US$20 per year; outside the USA $25. Library subscriptions in the USA are $40 per year; outside the USA, $45. All members and subscribers receive one volume of *Asiatic Herpetological Research* per year. Address all membership or subscription correspondence to Asian Herpetological Research Society, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA. Back issues of volumes 1-3 (1987-1990) are available from the same address at the same price per volume.

SERPENTES

THAMNOPHIS ORDINOIDES (Northwestern Garter Snake). **Reproduction.** Previous accounts of this species from the mid- and northern portions of its range indicate that clutch size ranges from 3 to 20 young with 8 to 12 being most common. The few records of clutch sizes above 15 have included both unfertilized ova and births of dead snakes in the counts. Mature females range in size from ca. 300 to 695 mm SVL though rarely exceed 600 mm SVL (Nussbaum, Brodie, and Storm 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. Press of Idaho. Moscow. 322 pp.; Stewart 1968. J. Herpetol. 2(3-4):71-86). We know of only one study that provides information on clutch size for *T. ordinoides* from the southern portion of its range. The average clutch size for 11 medium-sized females from southwestern Oregon was 5.2 (SE = 0.9) (Brodie 1989. Amer. Natur. 134(2):225-238).

On 23 August 1988 a gravid female *T. ordinoides* was captured at the edge of Hurdygurdy Creek (a tributary to the south fork of the Smith River), Del Norte Co., California. The snake measured 663 mm SVL and 784 mm TL; mass = 200 g. Sixteen ova were palpated in the field. The snake was brought to our laboratory, kept at normal (late summer, northern California) photoperiod and temperature conditions and provided with a "hot rock." She fed readily on large banana slugs (*Ariolimax* sp.) and shed once during her eight weeks in captivity. On 1 October 18 young were born - 17 live and one dead. Eleven of the live young were males and 6 were females. Neonates were measured shortly after their first shed and SVLs ranged from 136 to 148 mm ($\bar{X}$ = 142.9 mm); TLs ranged from 179 to 200 mm ($\bar{X}$ = 189.5 mm); masses ranged from 2.0 to 2.5 g ($\bar{X}$ = 2.09 g). These lengths and the sex ratio are similar to those observed for young of large females (>500 mm SVL) in the Willamette Valley, northern Oregon (Stewart op. cit.).

Submitted by **AMY J. LIND** and **HARTWELL H. WELSH, JR.**, USDA Forest Service, Pacific Southwest Forest and Range Experiment Station, Redwood Sciences Laboratory, 1700 Bayview Drive, Arcata, CA 95521, USA ●

TRIMERESURUS ALBOLABRIS (White-lipped Pit Viper). **Reproduction.** On 6 September 1989 a female *Trimeresurus albolabris albolabris* was captured in a mango tree in Bangkok, Thailand. She was housed in a large cage with two males previously captured at the same locality. Copulation was never observed but on 26 March 1990 she gave birth to 16 neonates. Five were stillborn, four more died on the second day, and on 29 March a deformed specimen was found dead. With the exception of the deformed neonate, each of the dead specimens was measured and the following SVLs recorded (mm): 155, 152, 157, 160, 161, 157, 164, 132, 165, and 163. Shedding began 1 April 1990, six days after birth, and by 6 April all but one of the five survivors had completed their first shed. On 6 April, eleven days after birth, the five surviving specimens were weighed. The masses (g) = 4.5, 4.5, 4.9, 3.85, and 3.7.

BOOK REVIEWS

Current Herpetology in East Asia, edited by Masafumi Matsui, Tsutomu Hikida, and Richard C. Goris. 1989. ix + 521 pp. Herpetological Society of Japan, Kyoto. Hardbound. Available from Dr. Richard C. Goris, Hatsuyama 1-7-13, Miyamae-ku, Kawasaki-shi 213, Japan for US $44.00, or from Dr. Tsutomu Hikida, Department of Zoology, Faculty of Science, Kyoto University, Kita-Shirakawa Oiwake-cho, Sakyo-ku, Kyoto-shi 606, Japan, for ¥5,500. Readers in Europe can pay in yen via International Giro addressed to Japan-China Herpetological Symposium Kyoto 8-57373, Japan.

This volume contains the proceedings of the Japan-China Herpetological Symposium, which was held in Kyoto, Japan, in July 1988. The 75 papers are organized in nine chapters and range from brief reports to detailed studies of ecology and systematics. Contributions from amateur and professional herpetologists are represented. Asian species, some of which are not widely known, are the primary focus of these studies, and they provide intriguing information about a herpetofauna that is little known by most Westerners.

The initial chapter, "Morphology," opens with two papers on neuroanatomy, a description of cranial nerves of the boa *Eryx miliaris* and of the innervation of the pit organs of pit viper *Agkistrodon blomhoffi*. These are followed by R. Aoki's description of the globular posterior teeth of the Chinese alligator and of two species of the crocodylid genus *Osteolaemus*. Brief descriptions of melanosomes in the skin of squamates and of the embryonic development of gonads of *Takydromus tachydromoides* complete the morphology chapter. Additional morphological topics are included in the chapter on "Systematics," including descriptions of the larvae of hynobiid salamanders.

The second chapter, "Embryology and Physiology," includes an assortment of topics. A description of captive rearing of the larvae of the Chinese giant slamander, *Andrias davidanus*, by G. Liu and H. Tang begins the chapter. A paper by M. Huang et al. describes general features of the embryonic development of the viviparous pit viper *Agkistrodon blomhoffi*. Photographs of most of the stages provide an impression of changes in body form, but they do not show details of structures such as the pit organs. The rate of embryonic development of *Gekko japonicus* at different temperatures is described by S. Tokunaga. Physiological studies are represented by descriptions of rates of oxygen consumption by eggs and hatchlings of the lizard *Takydromus septentrionalis* and by the Chinese alligator, as well as by descriptions of the effect of temperature on the viscosity of blood of cobras.

Phylogenetic studies are found in two chapters: A dozen papers grouped under the heading "Systematics" extend from a method of counting costal grooves of *Hynobius* to a study by T. Hayashi and M. Matsui of the family Salamandridae that employs allozyme data. "Karyology" receives a chapter of its own that includes an analysis of the phylogenetic relationships of species of *Hynobius* and descriptions of the karyotypes of Chinese and Japanese species of salamanders, frogs, and snakes.

Ecological topics are covered under several headings. "Biogeography and Faunistics" provides descriptions of the herpetofaunas of regions extending in size from single provinces through the Ryukyu Archipelago to "East Asia." Most of these papers are short, and several lack references to other studies.

Papers in the chapter on "Breeding Biology" describe the reproductive habits of individual species, providing useful information about their natural history. A few papers in this section address larger

questions, such as the treatment of sexual size dimorphism of the rhacophorid frog *Buergeria buergeria* by K. Fukuyama and T. Kusano. Additional information about reproduction appears in the chapter "Behavioral Biology," and includes a description of choice of nest sites by the pit viper *Trimeresurus flavoviridis* in enclosures and an interesting study of the mating strategy of male *Hynobius nebulosus*. This salamander breeds in small bodies of water, and fertilization is external. Territorial males defend egg-laying sites, and the largest males arrive at the breeding pools first and obtain the best territories. Nonterritorial males behave as sneakers, rushing toward ovipositing females and attempting to fertilize their eggs. Other behavioral topics include learned avoidance of an apparently unpalatable frog, *Rana rugosa*, by newborn *Elaphe quadrivirgata*.

Food habits of Okinawan frogs are described in a chapter on "Population and Community Ecology," and several papers consider the diets of snakes. In the most thorough of these, M. Hasegawa and H. Moriguchi compare the diets and food habits of two species of *Elaphe* on a series of islands off the eastern coast of Japan. *Elaphe quadrivirgata* is the most widespread of the six species included. On islands where it is sympatric with several other species of snakes, *E. quadrivirgata* is small and feeds exclusively on skinks, whereas on islands where it occurs alone or with *E. climacophora* it is large and eats a variety of prey including mammals and birds. Clutch size and egg size varied slightly in parallel with the island-to-island variation in body size.

A chapter on "Snake Venom and Snake Bite" concludes the symposium; papers in this section focus on the epidemiology and clinical treatment of snakebite, protective clothing, and the preparation of antivenom. An index includes both species and topics.

Clearly, herpetology is an active discipline in East Asia that is growing on many fronts. The region contains an assortment of fascinating animals, and this vloume provides an intriguing view of their biology.

Middle American Herpetology. A Bibliographic Checklist, by Jaime Villa, Larry David Wilson, and Jerry D. Johnson. 1988. i - xxxiii + three unnumbered pages + 131 pp., 91 color photographs arranged on 16 plates, 23 figures (two unnumbered), and one table. University of Missouri Press, Columbia. Hardbound US $35.

The passage from a manufacturing to a hurried, information-processing society has made the task of keeping abreast of herpetological literature formidable (not to mention costly). Indeed, the pleasure wrought by the arrival of a new publication is counterbalanced frequently by a feeling of anxiety at the prospect of its assimilation. Checklists, depending upon their accuracy, pose either a help or a hindrance to this process. They are best evaluated as tools rather than literature, and to adequately review one would entail as much work as its creation. This will not be an adequate review, but it will explore the reliability of a reasonably priced new checklist: *Middle American Herpetology* (MAH).

There are two types of checklists: those that treat unknown assemblages and comprise mostly novel data, and summary lists drawn from literature covering large regions. Although sometimes disdained for lacking originality, summary checklists should neither be published nor judged under this pretense; in fact, new data can be obscured when presented in this fashion. What these lists lack in invention is offset by the convenience they afford; their simple summaries are the object of heavy user-reliance.

Compilation of checklists is tedious and exacting, and these are the standards by which they should be judged. Properly done, and with timely geographic coverage, a checklist serves as an excellent jumping-off point for researchers, conservation and governmental agencies, students, hobbyists, and zoological park personnel. Moreover, the belated international environmental interest in biodiversity has resulted in a scramble for data in summary form.

Middle American Herpetology begins with a brief foreword by Henry Fitch followed by the color plates (an organizational novelty). The photographic quality is varied, as might be expected given the rarity of many taxa depicted; however, the photo of *Bothrops [sensu lato] lateralis* is the only one with serious color imbalance. Picture credits (nos. 51,64,72,74, and 77 were actually taken by J.A. Campbell) and usage (I was surprised to encounter one of my photographs in-print) seem to have been treated casually. There are several misidentifications (46 is *Amphisbaena fuliginosa*; 48 is *Chironius exoletus*; 58 is *Erythrolamprus mimus*). More importantly, the captions are an opportunity lost; instead of providing pertinent information (museum numbers, total length, specific locality data, etc.) they read like the text of a poorly prepared slideshow, containing a rambling admixture of local and English vernacular names. Statements like "this is the first published photo of a living specimen" are gratuitous rather than useful. Following the photos and table of contents, the authors outline their methods in the introduction. Each species citation is followed by: an indication of whether (and how) that species is listed in the Catalogue of the Neotropical Squamata (squamates), or the Catalogue of American Amphibians and Reptiles (nonsquamates); a section listing key literature pertaining to that taxon; references containing illustrations; and a distribution section which lists pertinent literature by country or region. When the status of an included species is uncertain, a note is added. Inasmuch as the book does not contain identification keys, a list by region of published keys is provided, and a table includes some other taxonomic works.

The introduction and authors' comments are in bilingual format which will be appreciated by hispanic users. The methods seem for the most part to be well considered. A problem with the "catalogue" entry is that it fails to include all species listed in the CNS but subsequently synonymized; thus the reader might confront a taxon in the CNS but be unable to locate it in MAH. Also, where no taxonomic change has occurred, the entry is supposedly deleted, but this has been done inconsistently. An update of changes since the CNS might best have been provided in tabular form, as researchers will use both books.

The "key" and "distributional" literature sections include theses, dissertations, other checklists, and numerous titles in preparation. The questions of their appropriateness aside, many are cited arbitrarily and erratically. For instance, Campbell (1982) contains a motherlode of distributional information, yet it is mentioned in passing. Key literature entries for many species include peripheral works in lieu of significant contributions; subspecies descriptions are usually excluded. Information provided on references containing illustrations is not encouraging in that frequent use of "none?" gives the impression the authors are uncertain about their literature search. The idea of providing

distributional references is a good one, but the selection suffers from inconsistencies, and the choice of citations could have been more rigorous. The transient nature of our distributional knowledge notwithstanding, I find the comments in CNS, Frost (1985), and Iverson (1986) to be of great help, and a similar approach (especially with regard to peripheral elements) would have benefitted the present work.

The authors provide useful remarks when the status of a species is uncertain, but many more should have been included. The list of keys and ancillary publications (Introduction and Table 1) is not complete, omitting basic works (among them: Uzzell 1973; Uzzell and Barry 1971; Pérez-Higareda and Smith 1986; Pérez-Higareda et al. 1985; Smith et al. 1986; McDiarmid and DeWeese 1977), and omitting many genera altogether. At least one work cited ("King et al. 1988") does not exist. Paradoxically, numerous titles mentioned nowhere in the text can be found in the Literature Cited. Perhaps, as implied in the title, the authors meant to include a bibliography.

What's in a name? A lot, if it appears in a checklist, where scientific names, correctly spelled and cited, are the acid-test. The number of nomenclatorial mistakes in *Middle American Herpetology* warrants this summary (errors in parentheses): misspelled family name (1), misspelled species name (26), misspelled author name (5), misused parentheses (51!), no author listed (13), wrong author (3). The issue of gender is always controversial, but *Bothrops* and *Sibon* are demonstrably masculine. Species are listed in their respective orders and alphabetized by family, and with the exception of the unused Alligatoridae, the authors explain controversial familial inclusions or deletions.

Middle American Herpetology treats 782 species of amphibians and reptiles, and the list is remarkably complete. A few exceptions are worthy of mention, however. Based on the literature the following species should have been included: *Eleutherodactylus antillensis* (Panama-introduced), *Rana brownorum* (Tobasco and Chiapas, Mexico), *Basiliscus galeritus* (Panama)., *Norops poecilopus* (Panama), *Sceloporus prezygus* (Chiapas, Mexico and Guatemala), *Hydromorphus dunni* and *Rhinoclemmys melanosterna* (Panama), and *Micrurus ancoralis* (Panama). The inclusion of *Siphophis longicaudatus* is inappropriate in that it is based on a personal communication; the fact that its putative presence in Panama represents a 6000-kilometer range extension is another matter. Extralimital species included erroneously are *Dendrobates fulguritus*, *Gonatodes annularis*, and *Norops sulcifrons*. The book would have benefitted from an *incertae sedis* so that excluded taxa (*Hyla bocourti*) or those included tenuously (*Norops rhombifera*, *Siphlophis longicaudatus*, among others), and other controversies could have been placed in perspective.

The occurrence of *Gastrotheca cornuta* in Costa Rica has yet to be established (Lamar and Porras, submitted); the authors include it based on a misinterpretation of Stejneger (1911). The gecko *Sphaerodactylus pacificus* is endemic to Isla Cocos, and the wideranging skink *Mabuya mabouia* should not be characterized as "an Antillean form." The type localities of *Norops intermedius* (Panama), and *Senticolis triaspis* (Belize) were excluded from their respective distributions.

Based on the literature, distributional errors abound; several sources and even the CNS have been misquoted more than once. Species known to occur in but not cited for Panama include: *Gastrotheca cornuta*, *Hyla pictipes*, *Coleonyx mitratus*, *Hemidactylus frenatus*, *Basiliscus plumifrons*, *B. vittatus*, *Norops pachypus*, *N. polylepis*, *Ameiva quadrilineata*, *Gymnophthalmus speciosus*, and probably *Lepidochelys kempi*. Neither *Bolitoglossa robusta* nor *Ninia sebae* has been reported from Panama. The authors excluded appropriately *Chironius fuscus* from Panama, but without comment. The lizard *Cnemidophorus lemniscatus* occurs in Costa Rica. The frog *Smilisca sordida* occurs in Nicaragua. The turtle *Lepidochelys olivacea* is found along the west coast of El Salvador, but the snake *Bothrops atrox* (=*B. asper*) does not occur in that country. The Guatemalan herpetofauna includes *Plectrohyla hartwegi*, *Sceloporus taeniocnemis*, *Geophis cancellatus*, *Rhinobothryum bovallii*, *Thamnophis cyrtopsis*, and *T. marcianus*, but does not include *Smilisca phaeota*, *Norops tropidogaster*, or *Pliocercus eu-*

Computerize Your
Field Notes and Collections

GECKO is a computer program for managing field notes and collections.

GECKO will allow you to:

Record genus, species, subspecies, number, locality, county, state, collector or observer, collection number and comments. Family, order and class are entered automatically.

Extract data for viewing, editing or printing by any combination of the above, e.g. iguanid lizard localities for Inyo Co, CA or all herps seen in Texas from June through August.

List data by order of entry, by date or phylogenetically.

Copy selected records to files for use with spreadsheets, word processors or data base programs.

Count number of species for all or part of the data base, e.g. number of species for 1988 or number of species of *Hyla*.

GECKO is very powerful, yet uses simple screen menus. It incorporates a master species list and is sold with your choice of the U.S. and Canadian list of herps, birds or mammals. Other species lists can be purchased separately and merged into a comprehensive list of terrestrial vertebrates. Lists can be easily edited to accommodate taxonomic changes or new species.

GECKO runs on IBM PCs and compatibles with 320K RAM and DOS 2.0 or later. $75 + $3 shipping. California residents add 6% tax. Please specify species list to be included. Additional lists are $25 each. Similar programs which use common names are available for all terrestrial vertebrates.

Sandpiper Software 153 Michele Circle, Novato, CA 94947

ryzonus. Additionally, *Chelydra serpentina* and *Thamnophis cyrtopsis* are found in Belize. The lizards *Norops limifrons* and *Sceloporus prezygus* occur in southern Mexico.

The puzzling inclusion of *Conophis pulcher*, which was synonymized (albeit inadequately) with *C. lineatus* by one of the authors (Wilson and Meyer 1982), makes one wonder how recently the text was revised...the synonymy was cited as being in preparation. The authors prudently placed in doubt the occurrence of *Bothrops [sensu lato] lateralis* in Nicaragua, owing to absence of verifiable specimens; one wonders why a similar stance was not taken with regard to *Laticauda colubrina*, and *Lachesis muta* from the same region (see also previous remarks about *Siphlophis longicaudatus*). Treatment of *Bachia blairi* and *B. pallidiceps* is confusing. The "key literature" cited for each (Dixon 1973) actually synonymized them. The resurrection of *B. blairi* occured in 1977 (McDiarmid and DeWeese), an unmentioned work. The *Scolecosaurus* cited by Dunn (1940) from Laguna de Pita, Panama, is probably referable to *B. pallidiceps*, as suggested by Dixon (1973). The authors request that unpublished material be sent for periodic updates which are planned, yet personal communications (used liberally throughout the present volume) were handled in a particularly cavalier fashion. In light of the aforementioned dangers of including new data in summary checklists, it would seem prudent to publish first.

The *Catalogue of the Neotropical Squamata* was a veritable state-of-the-union address for the region at the time of its first publication. Because it remains an important reference, and because of the rambling introductory critique of CNS in *Middle American Herpetology*, it is inevitable that they be compared. The modern situation admittedly is more complex, and the authors have negotiated a vast amount of literature during their compilation; this is offset by the much narrower scope of MAH. Technology has rendered simple what was recently arduous: the mechanics of writing and publishing. In that light, it is ironic that MAH is plagued with inconsistencies and poor editing. I found *Middle American Herpetology* to be more current, more detailed but less reliable than the Catalogue of the Neotropical Squamata, the stated shortcomings of which remain largely uneclipsed by this volume.

Now Available from SSAR

- Complete sets of HISS Herpetological Information Search Systems
Vol. 1, Nos 1 - 6 (1973) news - journal.

This publication is similar in format to Herpetological Review. It contains sections on Life History, Husbandry, Conservation, Geographic Distributions*, Book Reviews, and Original Research.

Subjects covered include - nest building in hylid frogs, effects of rattlesnake venom on rattlesnakes, case history of horned puffadder bite, courtship, eggs and young of the red-bellied turtle, and many others.

Cost of complete set - $10.00.
(HISS-titles and review Vol. 1, Nos 1 and 2 will be included)

To order, write to: Robert D. Aldridge, SSAR Publication Secretary, Department of Biology, St. Louis University, St. Louis, MO 63103, USA.

* these are included in the Index to Geographic Distribution Records in Herpetological Review: 1967-1986 by E. J. Censky, 1988.

Crocodiles, by Rodney Steel. 1989. Christopher Helm, London. Distributed by David and Charles, Inc. North Pomfert, VT 05053, USA ISBN 0-7470-3008-3.

Rodney Steel's new book is an updated version of Neill's flawed, yet classic work, *Last of the Ruling Reptiles*. This book is divided into chapters that consider some of the dominant themes in crocodilian biology, including anatomy, systematics, paleontology, and conservation. The book is illustrated with line drawings and photographs, and geographic distribution maps for the extant species are provided.

The book is riddled with trivia and amusing anecdotes about crocodilians - for instance Steel (p. 9) points out that "The aborigines of northern Australia believe that the spirits of their forbears lived on in the crocodiles of the region (commonly the highly dangerous saltwater crocodile), and believed that in the past their ancestors had turned themselves into crocodiles by pushing a firestick up their rectums."

In general there is much to be critical of in this book, even though the targeted audience is not the professional herpetologist. To begin with, an arrangement that was more clearly systematic would be of benefit but instead Steel discusses the taxa in a mishmash of subjects and taxonomic groups. Many inexcusable mistakes include the premise that crocodilians are the only extant species of archosaurs. Even the Victorians considered the extant Archosauria to be composed of birds and crocodilians. In fact there are more extant species of avian archosaurs than all other groups of living and fossil archosaurs combined.

My own expertise is in crocodilian paleontology and evolution. Here, probably because of my knowledge about the subject, I find the omissions and the errors most troublesome. I am surprised by this because, if Steel is an expert on any subject contained in this book, crocodilian paleontology would be it. After all he compiled one of the most-used treatises on the subject (see Steel 1973). His depiction of crocodilian orgins (p. 3) is virtually identical to those proposed decades ago by a variety of workers and contains no phylogenetic information. Several resolved phylogenies have been proposed recently (i.e. Clark 1986; Benton and Clark 1988; Norell 1988; Densmore 1983), that depict the phylogeny of these taxa and give evidence for these relationships. His use of the grade levels of Protosuchia, Archeosuchia and Mesosuchia is a real blast from the past.

Steel also perpetuates the myth that crocodilians are living fossils and are essentially unchanged over the last 200 million years, yet further on he argues that the extant crocodilians are much more advanced than their Mesozoic relatives. I find it interesting that no extant genus can be identified farther back than the Oligocene, and even this should probably be revised to Miocene.

Several glaring errors concern specific fossils. On p. 38 Steel states that "The oldest eusuchian so far discovered appears to be *Hylaeochampsa*, which comes from the Hastings Sand of Sussex . . . The specimen was found by the famous 19th century physician Gideon Mantell . . . Unfortunately, the remains of *Hylaeochampsa*, contained in a nodule of ironstone, comprise only a dozen or so vertebrae that seem to be of characteristic eusuchian procoelus type, together with what looks like a cranium. It is not certain that the vertebrae and the fragmentary skull belong to the same animal, and the palatal structure cannot be elucidated to find out if the pterygoid bones contribute to the formation of the secondary palate."

Steel seems to have confused the type specimen of *Hylaeochampsa* with the poorly known *Heterosuchus*. These specimens were collected about 100 kilometers apart and in some literature have been synonomized (Romer 1956). The cranium of *Hylaeochampsa* is actually a very fine specimen (collected by Fox not Mantell), preserved in a fine clay (not ironstone), and from the Wealden Formation of the Isle of Wight (not the Hastings Sand near Hastings). The type specimen of *Hylaeochampsa* has been figured repeatedly for the past 115 years. The remarkable character of the palate makes this specimen a true eusuchian with unambiguous pterygoid contribution to the secondary palate.

Steel also cites that "of Lower Cretaceous age is a single procoelous vertebral centrum . . . which is probably crocodilian and hence eusuchian." This logic does not follow, because procoelus vertebrae are not unique to the Eusuchia (Norell and Clark, in press), they also occur in some Goniopholidids, atoposaurs (Steel 1973), and in the caudal vertebrae of *Bernissartia*, all taxa that Steel considers to be "mesosuchians." On p. 150, Steel figures a well-preserved skull with the caption "The fossil skull of a teleosaur *Steneosaurus bollensis*, from the Lower Jurassic of Holzmaden, Wurttemburg." In reality, this skull is a British Museum specimen of *Pelagosaurus typus* from Caen, France originally described and figured by Eudes Deslongchamps in a classic monograph.

These errors and the archaic systematics and format of the book render it of little use to the professional herpetologist or even informed amateur from my perspective. It should join the ranks of the not-too-scientific coffee table stack. One wonders, considering all of the errors, spurious interpretations, omissions, and dated material whether such a book does more harm than good.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to rteview herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations and photographs. Manuscripts submitted must be typed, double spaced, on 8.5X11 inch paper, and should be sent in duplicate. We encouerege submissions on Macintosh disks, though we can also work with TEXT (ASCII) files submitted on IBM and compatible floppies. **Herpetological Review** is composed on a Macintosh SE using Microsoft Word, which accepts files from several other word processor applications. Format your documents full-page width; we will fit to **HR** format. Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8X10 inches black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. Herpetological Review will accept commercial advertising. Rates and copy information are available from the advertising manager. Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats. Contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

Society For The Study Of Amphibians And Reptiles

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (4 issues annually), **Herpetological Review** (4 issues annually), and occasional issues of **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1990

Student member.....$25.00*	Sustaining member.....$50.00*
Regular member.....$35.00*	Contributing member.....$75.00*
Institutional subscription.$60.00*	Life member..(see below)...$600.00*

***Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00.
Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, draft on a US bank, or by Mastercard or Visa (include account number and expiration date of credit card). Life memberships may be paid in 3 consecutive payments

Subscriptions to Herpetological Review only are available for $12.00 annually. Subscriptions outside of the US require a surcharge of $8.00 for air delivery if airmail is desired. Subscribers to HR only are not members of the Society.
Catalogue of American Amphibians and Reptiles: subscription $15 annually ($3.00 air delivery surcharge if airmail is desired.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

NEWSNOTES

ANATOMICAL RECONSTRUCTION PROGRAMME

A computer programme is currently being developed which will enable researchers to produce 3-dimensional reconstructions of solids from the outlines of sections. ANATRECON (= Anatomical Reconstructions) permits separation of parts by color, and the programme will work on all computers compatible with IBM PCs. English, Swedish, and German versions will be available. Anybody who is able to work with any standard word processor will be able to use this programme. The price of the programme is DM 2000.

For further information, contact Dr. Zbynek Rocek, Department of Paleontology, Charles University, Albertov 6, Prague 2, 12843 Czechoslovakia. ●

GOPHERUS LIBRARY ESTABLISHED

A library has been established at Archbold Biological Station near Lake Placid, Florida, for the purpose of accumulating, indexing, and disseminating information on all aspects of the biology of tortoises of the genus *Gopherus*. It is hoped that the new *Gopherus* Library will become a comprehensive repository for information on all four living species in this genus.

The nucleus of the literature collection thus far consists of all of the references cited in an earlier bibliography and supplement on the genus (Douglass 1975, 1977), totaling 644 entries. A detailed subject code is available for these references.

Mailings of reprints and of informal research reports are solicited. Photocopies of difficult-to-obtain articles will be made available to participants at a nominal fee (i.e., at cost). Mailings should be directed to: *Gopherus* Library, c/o Mr. F. E Lohrer, Librarian, Archbold Biological Station, Lake Placid, FL 33852, USA.

Should participation and interest be sufficient, preparation of a second bibliographic supplement may be considered at some time in the future. This would include a detailed subject index to the contents of material appearing since the 1975 and 1977 installments. ●

PELOBATIDAE RESEARCH GROUP

A Pelobatidae Research Group is forming for facilitating exchange of information via workshops and newsletter. The purpose of the group is to encourage comparative research on different species of Pelobatidae and to improve and develop methodologies. A list of "who's who" in Pelobatidae research is being prepared and will be distributed among PRG members. For further information contact: Sarig Gafny, Institute for Nature Conservation Research, Tel-Aviv University, Ramat-Aviv 69978, Israel (Fax. No. 972-3-5413752) ●

WILDLIFE REHAB GRANTS

The National Wildlife Rehabilitators Association announces its small grants program. This program makes available two $1,000 research grants in the field of wildlife rehabilitation. Each may be applied to one large project or several smaller research projects each totaling less than $1,000.00. Applicants must demonstrate financial need and submit a typewritten proposal that includes: name(s) and resume of personnel involved, objectives of the project, a brief description of how the project will be carried out, a brief literature review and an itemized budget.

An annual report on progress is required. It is expected that those receiving NWRA support will present the results of their projects at an NWRA national meeting within 2 years of receipt of the grant.

The deadline for submitting proposals for research grants is **December 15** of each year. Recipients will be announced at the NWRA annual meeting in February and in writing.

Proposals should be submitted to: Mark Pokras, DVM, Tufts University School of Veterinary Medicine, Wildlife Clinic, 200 Westboro Road, North Grafton, MA 01536, USA. ●

MEETINGS

ASZ ANNUAL MEETING

The 1990 Annual Meeting of the American Society of Zoologists with the American Microscopical Society, Animal Behavior Society, The Crustacean Society, International Association of Astacology, and Society of Systematic Zoology will be held at the Marriott Rivercenter Hotel in San Antonio, Texas, during the traditional post-Christmas period, 27-30 December.

An *August 1* deadline for receipt of abstracts of papers (oral or poster presentations) has been set. Posters are particularly encouraged.

Symposia and workshops presently scheduled are: (1) Mechanisms of Mate Choice, (2) Neural Aspects of Reproductive Endocrinology: Old Questions, New Approaches, (3) Neuroendocrine Strategies in a Tropical Environment, (4) Animal Immunity: Bio-

markers for Assessment of Risks from Environmental Xenobiotics, (4) Amphibian Metamorphosis, (5) The Complete Crab: Physiological Ecology of Everyday Life and Special Events, (6) The Evolution of Viviparity in Vertebrates, (7) Life History and Evolution in Uncertain Environments, (8) New Perspectives in Marine Soft-bottom Ecology, (9) Amphibian Relationships: Phylogenetic Analysis of Morphology and Molecules, (10) Ecological Morphology: Integrative Approaches in Organismal Biology, (11) Development and Macroevolution, (12) Computational Approaches to Comparative Neurobiology (ASZ), (13) "Aschelminthes" Revisited: A Refresher Course (AMS), (14) Animal Care and Use Committees in Zoological Research Departments (ASZ), and (15) History of Carcinology (TCS).

Meeting plans include an art exhibit, films and special programs on (1) Biologists and the Media, (2) The Process of Publishing Papers, and (3) Improving Visual Communications in Science: Posters, Slide Presentations and Quantitative Data Displays. Several socials, commercial exhibits, a Job Placement Service and a Babysitting Service will be arranged. The Housing and Registration deadline is November 15; forms will be available in early October.

This meeting is hosted by Trinity University and University of Texas Health Science Center with Thomas L. Koppenheffer and Mary K. Vaughan co-chairing the Local Arrangements Committee.

For more information contact: Mary Adams-Wiley, Executive Officer, American Society of Zoologists, 104 Sirius Circle, Thousand Oaks, CA 91360; FAX (805) 492-0370, telephone (805) 492-3585. ●

S. E. H. MEETING
BUDAPEST • 1991
First Announcement

According to the decision of the 5th Ordinary General Meeting held in Canterbury, UK, the 6th meeting of the Societas Europaea Herpetologica is to be held in Budapest in 1991.

Meeting Place: House of Agricultural Societies ("Hotel Agro"), Budapest, Hungary.

Date: 19-23 August 1991.

All previous S.E.H. traditions will be followed, i.e., four days of two concurrent scientific sessions, one day of field excursions, poster sessions, roundtables and workshops, technical facilities, etc. Room accomodations will be offered on three different price levels, according to demand.

A circular will be sent to those who wish to participate in the meeting. Request before 1 September 1990, at this address: Dr. Zoltán Korsós, Zoological Department, Hungarian Natural History Museum, H-1088 Budapest, Baross u. 13, Hungary.

NEW ZEALAND HERPETOLOGY MEETING

The Society of Research on Amphibians and Reptiles in New Zealand (SRARNZ) will hold an AGM and Conference in Whitianga, New Zealand, 24-27 November 1990. Field trips are planned to sites where two species of native frogs (*Leiopelma*) occur and to the Mercury Islands, where the tuatara and ten lizard species occur.

Contact Dr. David Towns, Conservation Sciences Centre, Department of Conservation, Box 10-420, Wellington, New Zealand ●

REGIONAL SOCIETIES

SIXTH ANNUAL MIDWEST HERPETOLOGICAL CONFERENCE

The Sixth Annual Midwest Herpetological Conference, hosted by the Minnesota Herpetological Society, will be held in Minneapolis, Minnesota at the J.F. Bell Museum of Natural History on 12-14 October 1990.

The planning committee has worked with the University's Bell Museum and the Nongame Wildlife Program to develop an exciting program. The program includes talks and displays on the conservation, propagation, and natural history of amphibians and reptiles that are of interest to persons in the Midwest.

For registration information please write to: 1990 Midwest Conference, Minnesota Herpetological Society, Bell Museum of Natural History, 10 Church St. S.E., Minneapolis, MN 55455, USA. ●

CHICAGO HERPETOLOGICAL SOCIETY $2000 PRIZE COMPETITION

The Chicago Herpetological Society is looking for high quality, original material not elsewhere published that deals with various aspects of herpetology. Towards this end the Society is offering cash prizes for the best material to appear in Volume 25 (1990) of the CHS *Bulletin*, a monthly publication. The following four prizes will be awarded:

$1000 for the best article
$500 for the second place article
$250 for the third place article
$250 for the best black & white photograph or drawing

Article topics could be, but are not limited to: captive breeding and husbandry; a faunistic survey or other field work; an historical account of herpetologists or the animals they studied; or an exciting personal adventure in herpetology. Articles must be typed double spaced, have adequate margins, and be submitted in duplicate. Articles submitted in the form of an ASCII file on a floppy disk would be greatly appreciated. Photographs submitted with or without articles must be 5x7 inches (or larger), glossy, black & white prints. Data on the subject must accompany the photograph in a typed caption of less than 100 words.

Submission of articles and photographs gives the CHS the right to publish the material. Awards will be announced in the February 1991 *Bulletin*. All material should be submitted to: Publications Secretary, Chicago Herpetological Society, 2001 N. Clark Street, Chicago, IL 60614. ●

FEATURES

ON THE LEGAL STATUS CONCERNING THE PROTECTION OF AMPHIBIANS AND REPTILES IN GREECE

It is a well known fact that human populations can greatly influence the populations of amphibians and reptiles. For the last 15 years European research has verified that there has been a dramatic decline in amphibian populations, which varies in different ecosystems (Honegger 1978). According to Stumpel & Podloucky (1984) the amphibians and reptiles have a small radius of action, and accordingly, a smaller habitat. This implies that even small-scale human activities can influence these habitats on a large scale.

Amphibians and reptiles are exposed to a wide variety of threats, such as modern agriculture, drainage and flooding and road construction. In addition, chemical pollution of water and soil have negatively affected many species (Heusser 1974; Wermuth 1975; Berger 1987). In response to this, a series of laws and international treaties has been developed to protect certain amphibians and reptiles. This paper presents the legal status of amphibians and reptiles in Greece. Some proposals concerning the improvement and more effective applicability of the existing laws are also presented.

The Greek fauna includes 16 amphibian and 52 reptilian species (Sofianidou 1980, 1988) (Table 1). Greece is considered to have one of the richer herpetofaunal assemblies in Europe due to the large number of species as well as the large populations. However, the destruction of biotopes, as well as the uncontrolled collection and trade of some species, have created many problems (Asimakopoulos 1989).

For the last 15 years, the Greek government has tried to renew the legal status concerning the protection of the environment. The main law for the protection of nature is the N.1650/86. According to it, protected species can be designated by competent ministers. However, amphibians and reptiles are not protected under this law. More comprehensive protection is given by the presidential order 67/80 (ΦE.K. A/23/30-1-81) "for the Protection of the Indigenous Flora and Wild Fauna." It includes 10 amphibians and 38 reptiles (Table 1). Special care is given to marine turtles. Presidential order 617/80 (Φ.E.K. Α΄ 163/18-7-80) gives protection to three species: *Caretta caretta, Chelonia mydas* and *Dermochelys coriacea*. Two ministerial orders concerning *Caretta caretta* were also published as a result of public pressure: 88208/3723 (Φ.E.K. Δ΄37/29-1-87) and 18670/777/29-2-88 (Φ.E.K. Β΄137/10-3-88). These decisions protect the egg-laying beaches in Zakynthos Island.

In addition to these national laws, the Berne Convention (Convention on the Conservation of European Wildlife and Natural Habitats, 19-9-83) was signed by Greece and has the power of law after 1-10-83 [law N.1335 (Φ.E.K. A' 32/14-3-83)]. European Parliament has also published two rules enforced in Greece, as well as in the other countries of European Economic Community (E. E. C.) Rule 3626/82 is for the international trade of endangered species, while rule 3418/83 establishes some procedural matters concerning the application of the former rule. In the appendices of these two rules 9 species are included, which belong to Greek herpetofauna: 3 tortoises, 1 lizard, 3 marine turtles and 1 snake (Table 1).

It is worth mentioning the Ramsar Convention (Convention on Wetlands of International Imporance) held at Ramsar, Iran on 2-2-71. In Greece, it is in power, since 1974, with the law N.191/19-11-74 (Φ.E.K. 350/A/74). According to this law 13 Greek wetlands of international interest are protected. This represents an additional, indirect but essential legal protection to the populations of amphibians and reptiles inhabiting these wetlands.

A notable point is that, with the exception of the ministerial decisions for *Caretta caretta*, the laws are much too general. They also do not cover an important part of the Greek herpetofauna. Species that have been classified by the Conservation Committee of S.E.H. as "threatened" (Stumpel & Podloucky 1984) are not included in the appendices of the laws. But the most serious problem is that the laws are not enforced except on some occasions concerning *Caretta caretta* when the laws worked only under the pressure of public opinion. *Caretta caretta* is the most famous reptile species in Greece today and its conservational problems are well known, thanks to the members of "Sea Turtle Protection Society" (Margaritoulis D. 1982, Veniselou E.L. 1987, Arianoutsou M. 1988).

The main reason for this ineffectuality of laws comes from the lack of information among people, state services and civil authorities. So, the collection of all species for scientific purposes is completely uncontrolled. This happens even in areas with special protection status, such as the national parks and the wetlands included in the Ramsar Convention. It is also a very common phenomenon that tourists collect tortoises for pets or for human consumption and that frogs are taken for the delicatessen trade.

It is also worth mentioning the remarkable and profitable trade in frogs for food in Greece. Every year large quantities of frog legs, fresh or canned, are exported to Western Europe. The collection concerns the species *Rana ridibunda, Rana epeirotica* and their hybrids and takes place by agreement of the ministers of Agriculture and commerce. For example, in 1988 the E4/2597/91 3/23-5-88 decision was published which allowed the collection and exportation of 70 tonnes of frogs during the period 1-6-88—31-10-88. The mass of each collected specimen was supposed to be at least 80 g. But the restrictions were very difficult to enforce because of the poor control by the services of Ministry of Agriculture.

From time to time, licences have been also given for collection of small numbers of the tortoises *Testudo graeca* and *Testudo hermani*. Two cases of illegal collection and exportation of these species have been reported. These specimens were returned to Greece thanks to the efforts of customs of Holland.

In view of the above, it follows that there is a need to improve the legal protection of additional amphibians and reptiles in Greece, particularly those species which are included in the appendix of the Conservation Committee of S.E.H. (Stumpel & Podloucky 1984). To be more concrete, a special ministerial order with a complete list of protected amphibians and reptiles must be developed and the N.1650/86 must be activated. That ministerial order must prohibit the collection, trade and destruction of habitats of the species (except on specified occasions) and must also provide penalties for the transgressors.

There is also a strong need to inform all the relevant services (Ministries of Environment, Agriculture, Commerce and Navigation) and the civil authorities about the present laws concerning the protection of amphibians and reptiles. It is also important to alert all involved in the vacation trade that there are laws in force which protect native amphibians and reptiles and that it is illegal to take or export certain taxa.

Yet the real need remains: to make the public sensitive to these matters because public opinion is the only way to achieve strict laws and then to enforce them.

HELMINTH PARASITES INDICATE PREDATOR-PREY RELATIONSHIPS IN DESMOGNATHINE SALAMANDERS

Many ecologists overlook the potential for using the presence or absence of helminth parasites as biological indicators of trophic interactions between free-living animals. Many helminth species have complex life cycles and commonly exploit food web relationships, particularly predator-prey interactions, to effect their transmission. Consequently, the presence of certain parasites can provide valuable information on the feeding habits and patterns of habitat use of their hosts. In this report I review information on larval helminth parasitism that indicates predator-prey relationships involving desmognathine salamanders in mountain streams of the southeastern United States. In addition, new data are presented relating parasite transmission dynamics to features of desmognathine ecology.

Leurognathus marmoratus, Desmognathus quadramaculatus, D. monticola and *D. ochrophaeus* form a series, inhabiting an ecological gradient spanning aquatic to terrestrial habitats (Dunn 1926; Hairston 1949, 1986; Martof 1962). Progressive reductions in body sizes and duration of larval period accompany increasing terrestrialism. *Leurognathus marmoratus* is the most aquatic of the four species. Within the genus *Desmognathus*, there is an evolutionary trend towards terrestrialism. *Desmognathus quadramaculatus* is the largest and most aquatic of the three congeners; *D. ochrophaeus* is the smallest and most terrestrial, and *D. monticola* is intermediate in body size and degree of terrestrialism. Tilley (1968) and Hairston (1980, 1986) stress the importance of predation as the predominant force underlying the evolutionary trend of terrestrialism in *Desmognathus*. They argue that predators of salamanders are more common in streams than in the forest. Accordingly, there has been strong selective pressure on salamanders to become more terrestrial, thus reducing the effect of predation by large aquatic salamanders and fish. Hairston (1986) demonstrated that *D. ochrophaeus* is an important prey species for larger congeners. However, few investigators have commented on the presence of other vertebrate predators of salamanders (but see Forester 1978; Hairston 1980).

Goater et al. (1987) studied the helminth parasites of desmognathine salamanders from southern Appalachian mountain streams in the Nantahala National Forest (Macon County, NC). They demonstrated that parasite distributions in these four salamander species could be correlated with host size (age), diet and habitat preferences. In their study, three larval parasite species were recovered from metamorphosed salamanders. Included were two trematodes, *Didelphodiplostomum desmognathi* (Rankin) (=*Diplostomulum desmognathi*) and *Metagonimoides oregonensis* Price, and larvae of an unidentified ascaridoid nematode. *Didelphodiplostomum desmognathi* is an intestinal fluke which uses the opossum, *Didelphis virginiana*, as its definitive host (Miller and Harkema 1970), while *M. oregonensis* matures in raccoons, *Procyon lotor*, and mink, *Mustela vison*, in North Carolina (Harkema and Miller 1964; Miller and Harkema 1964). The larval nematode is believed to mature in reptiles (Fischthal 1955), possibly ringneck snakes, *Diadophis punctatus*, which were observed around streams and seepages in the areas sampled and have been implicated as potential predators of desmognathine salamanders (e.g. Forester 1978).

The prevalence of nematode larvae in *D. quadramaculatus, D. monticola* and *D. ochrophaeus* was 7.8, 11.2 and 1.9% respectively. Metacercariae of both trematode species were recovered from >70% of the *L. marmoratus* and *D. quadramaculatus* collected from Curtis Creek, a stream containing their first intermediate host, the gastropod, *Goniobasis proxima*. Host specificity was evident since none of the *D. monticola* (n = 125) and *D. ochrophaeus* (n = 107) harbored trematode larvae. The short, 9-10 month larval periods of these latter two salamander species (Bruce 1989) may facilitate host specificity by preventing long-term exposure to penetration by trematode cercariae. Moreover, the larvae and adults of *D. ochrophaeus* and *D. monticola* are found mostly in seepages and springs and so are not in ecological overlap with the cercariae released from *G. proxima* found in strongly rheocolous microhabitats in streams. When Curtis Creek was resampled during the summer of 1988, 100% of the larvae of *L. marmoratus* (n = 6) and *D. quadramaculatus* (n =8), harbored metacercariae of both trematodes. Thus, cercariae of these trematodes are shed from snails in streams and accumulate as metacercariae during the prolonged three or four year larval periods (Bruce 1985, 1988) of these two primarily aquatic species. Prevalence and density of the parasites are high because of this long-term feature of transmission dynamics.

This study emphasizes the importance of understanding host biology and parasite specificity before interpreting data as evidence of predator-prey interactions. For example, errors in larval selection often lead into "dead-ends." That is, some hosts may be physiologically appropriate for the development of a parasite but do not present the ecological circumstances to make the parasite available to the next host. Since neither parasite has been reported from fish and none was recovered during necropsy of two fish species (*Cottus bairdi, Salmo gairdneri*) in Curtis Creek, this is not a likely transmission route.

Larvae of several anuran and salamander species are capable of acting as second intermediate hosts for *M. oregonensis*, under laboratory conditions (e.g. Lang and Gleason 1967). However, in Appalachian streams anurans are rarely found and only those salamander species which are in ecological overlap with *G. proxima* can be infected. Thus, salamanders are not "dead-ends" for these trematodes; infecting aquatic salamanders is the only mode of transmission to infect mammals and account for the observation of infected snails in streams.

Host-parasite interactions may represent a long-standing coevolutionary relationship (Price 1980). The evolution of complex life cycles in helminth parasites often implies an intimate coevolutionary history between predator and prey. Since the larval helminths described herein use salamanders as intermediate hosts, it is clear that desmognathine salamanders are currently a prey source for certain mammalian predators (and possibly snakes) along mountain streams of the southeastern United States. Moreover, it is evident that transmission dynamics of the parasite species are closely linked to aquatic habitats. This observation is significant for it supports Hairston's (1980, 1986) notion that predation pressure is greater in streams than in adjacent terrestrial habitats.

I suggest that investigators incorporate knowledge of the biology of helminth parasites as an additional basis for understanding the evolutionary ecology of vertebrates. Information provided by parasites is particularly valuable for vertebrates which are secretive, nocturnal or fossorial (certainly the majority of amphibians and reptiles) as field observations are not easily made. Even in such a well-studied group as the desmognathine salamanders, the presence of larval parasites has provided an effective means for tracing current food web relationships.

AN EARLY REPORT OF ENVIRONMENTAL TEMPERATURE CONTROL

Reviews of environmental temperature control of "ectotherms" suggest that this phenomenon was discovered through the efforts of R.B. Coles and C.M. Bogert and first reported in a series of seminal papers in 1938 and 1939. Some time later, it was noted that Sergeyev had published on the issue two years earlier; however, the paper remained unknown to non-Russian speaking scholars.

As part of a literature search on an unrelated topic, I stumbled across a German paper by Paul Krüger (1929). It reports on experiments mainly carried out in the early 1920s and apparently unknown to and uncited by the authors of the more recent studies.

Krüger documented (1) that poikilotherm "skin" absorbed various wave lengths (of light) differentially and (2) that the depth of penetration of the energy involved differed with wave length. He (3) noted numerous cases in which pigmentation patterns reflected absorptivity and (4) showed that the pigmentation changes occurred in animals apparently as part of an adaptive regime. Measurements of wave length and absorption proceeded with the appropriate physical techniques, although description of the equipment documents how much easier many of these measurements have now become. Issues such as the lag time of thermometers were discussed.

The studies also (5) document the (negligible) effect of the heat storage within the animal, and of conduction and convection, and (6) the substantial potential for heating of the animal due to reradiation from the surface. Animals were exposed to sources of heat throughout the day and their body temperatures correlated with details of the rapidly changing radiation regimen, measured by thermocouples.

Krüger is known for the "discovery" that amphibian muscle contained both fast and slow fibers, a discovery that was ignored for many years, although it is now unquestioned. I suspect that it was this second discovery that led him to depart from further analyses that would inevitably have convinced him of the generality of the preferred temperature phenomenon, which is alluded to here but not stated explicitly.

The point of reviewing the paper this late is not just to note the priority of discovery; this can hardly be important to any of the people involved. Rather it seems useful to note again that the careful observations and experiments reported in the older literature retain the potential for providing insights into significant, and sometimes overlooked, natural phenomena.

FEEDING ECOLOGY OF THE SIX-LINED RACERUNNER (*Cnemidophorus sexlineatus*) IN SOUTHERN FLORIDA

Although information is available on the feeding ecology and dietary preferences of many species of North American teiid lizards (Milstead 1957; Mitchell 1979; Best and Polechla 1983; Pianka 1986; Smith 1989), there are relatively little data available for the six-lined racerunner, *Cnemidophorus sexlineatus,* in southern and central Florida (Wilson and Porras 1983). Previous studies have focused on the natural history of populations from the central and western boundaries of its range (Fitch 1958; Hardy 1962; Clark 1976) as well as from South Carolina (Bellis 1964). Mushinsky (1985) provided information concerning the effects of fire on population densities of *C. sexlineatus* from the Tampa area. This study provides information on stomach content analyses for *C. sexlineatus* from Hillsborough County, Florida.

All animals were collected during June through August, 1988-1989, by noosing or though the use of pitfall traps as described previously by Punzo (1974a, b) and Mushinsky (1985). Pitfall traps were checked daily. The lizards studied were adult males and females (54.1 - 61.1 mm SVL). The study site was located near Lettuce Lake Park, Hillsborough County, Florida (28° 06'N, 82° 21'W) and consisted of a well-drained sandy substrate which supported xerophytic vegetation including turkey oak (*Quercus laevis*), live oak (*Q. geminata*), slash pine (*Pinus palustris*), saw palmetto (*Serenoa repens*), grasses (*Andropogon* spp., *Aristida stricta*), legumes (*Baptista lecontei*) and composites (*Aster* spp.).

Following capture, lizards were taken to the laboratory where they were measured, weighed and sexed. Stomach contents were collected using the stomach-flushing technique described in detail by Legler and Sullivan (1979). Following this procedure, most lizards were given individual identification numbers by toe clipping and released at the original site of capture for future demographic studies. Voucher specimens were deposited in the Vertebrate Collection at the University of Tampa (UTMC 1127-1143). Only lizards captured for the first time were used in stomach analyses. Prey items were identified to Order and Family wherever possible.

The results (number of prey, proportion of total sample, percent volume and frequency) are listed in Table 1. There were no significant differences between sexes (Chi Square, $p > 0.25$) or between the years and months during which sampling was conducted (Two Sample Means Test, assuming unequal variance, $p > 0.15$; Sokal and Rohlf 1981). About 96% of all arthropod prey items are associated with a terrestrial or fossorial habitat whereas only about 4% represents arthropods commonly found above the ground. This suggests a strong preference for terrestrial foraging in this species, at least from this study area.

Individuals consumed a wide variety of ter-

restrial arthropods. Termites (Isoptera) alone accounted for ca. 49% of the total number of prey items and were found in 97.8% of all stomachs examined. Although termites are frequently abundant over very short time intervals due to species-specific emergent patterns of reproductives, no significant seasonal differences were found in the percent composition of any prey items during the course of this study. Thus, termites represent an important component of the diet for *C. sexlineatus* during summer months in southern Florida.

Over 50% of the stomachs examined contained carabid, scarabaeid and tenebrionid beetles, lepidopteran larvae, orthopterans such as gryllids and tettigoniids, and spiders. The majority of prey biomass (expressed as percent volume) was contributed by carabid and scarabaeid beetles, termites, crickets and other unidentified Orthoptera, and spiders. Although Isoptera have been found to be a major dietary component in other populations of *C. sexlineatus* over shorter seasonal periods (Fitch 1958; Hardy 1962) as well as in other North American teiids, the degree of representation of other insect and arthropod taxa can vary (Best et al. 1983; Anderson and Karasov 1988). This may reflect differences in arthropod species diversity between different geographical regions. The larvae of elaterid, scarabaeid and carabid beetles are generally found just beneath the ground surface, under rocks or beneath leaf litter and yet were readily found and consumed. Most of the spiders found in the stomachs of *C. sexlineatus* were ground-dwelling, wandering types such as diurnal lycosids and oxyopids (Punzo 1989). Spiders which are associated with flowers or found above ground, such as thomisids, orbweavers, salticids and theridiids, which were observed to be very common in the study area, were not found in any of the stomachs examined. In addition, commonly occurring ground-dwelling insects and other arthropods with well-known chemical defenses such as blister beetles (Meloidae), velvet ants (Mutillidae) and millipedes, were also excluded.

Table 1. Analysis of stomach-flush samples from *Cnemidophorus sexlineatus*. A total of 92 stomach samples from different lizards were analyzed, all containing food. The results are expressed as number of prey, proportion of total sample, percent volume and frequency (percent of lizard stomachs containing a particular prey item). There were no significant differences in dietary composition as a function of season, year or sex.

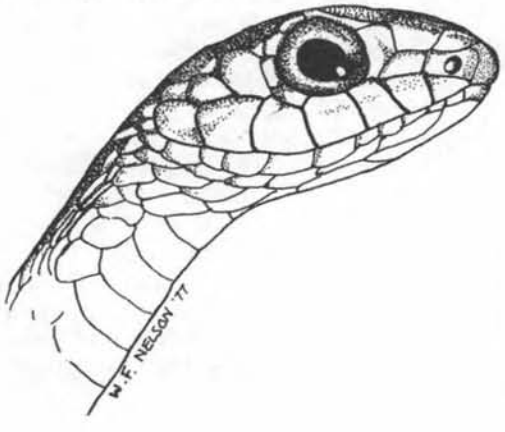
TECHNIQUE

MAGNETIC LABEL HOLDERS FOR METAL SHELVES



Metal shelves are widely used for storing jars containing specimens preserved in fluid. This note describes a label system that allows the shelf labels to be moved easily to allow for growth and expansion.

Clear, plastic-tube label holders, six in. long, from ½ to 1½ in. high, and with adhesive strips for mounting, are available from several library supply catalogs (I used those from Highsmith Co., P.O. Box 800, Fort Atkinson WI 53538). Thin, flexible sheets of rubberized magnetic material are available locally from businesses specializing in automobile and truck door signs. Strips from this sheet-magnet can be cut easily and stuck to the adhesive strip of the label holders. The label holders can be cut to required length with scissors or a paper cutter.

Paper labels in large type (18, 24, 30 point or larger) can be printed with a laser-jet printer, and slipped in the label holders. Using the thick paper label stock supplied with the label holders provides bulk inside the label holders and prevents the thin, printed labels from falling out. It is efficient to first prepare the label holders with magnetic strip and paper insert at their full length before trimming them for the printed labels.

The result is a magnetic label that can be read at a distance and moved as the collection is rearranged. These magnetic label holders are useful wherever metal shelves or metal cabinets are used except in collections accessible to the general public where the temptation to rearrange or remove the label holders might be great.

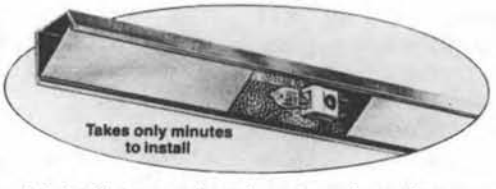
GEOGRAPHIC DISTRIBUTION

HERPETOLOGICAL REVIEW publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in Collins, 1990, *Standard Common and Current Scientific Names for North American Amphibians and Reptiles, Third Edition*, Herp. Circ. 19: 1–41), LOCALITY (use metric for distances), DATE (day-month-year), COLLECTOR, VERIFIED BY (cannot be verified by an author — curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al., 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology*, Copeia 3: 802–832) AND CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full — spell out state names — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen only when the live specimen could not be collected (e. g. it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive such as large turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the catalog number(s) must be included in the same manner as a preserved record. All specimen identifications must be verified by another authority (not one of the authors).

Please submit any geographic distribution records in the **standard format only** to: Joseph T. Collins or Darrel Frost, Section Co-editors, Museum of Natural History — Dyche Hall, The University of Kansas, Lawrence, Kansas 66045-2454 USA. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format.



Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic Distribution: *Lampropeltis triangulum multistriata*. SSAR Herp. Review 19: 100.

CAUDATA

AMBYSTOMA JEFFERSONIANUM (Jefferson Salamander). USA: OHIO: Ashtabula Co: Trumbull Twp. (41° 42' 33 "N, 80° 53' 03" W). 28 March 1989. T. O. Matson. Verified by

THE HERP LIGHT

Replace awkward light fixtures placed on top of reptile cases with this streamlined, custom-cut halogen light track from Edwin Products. Utilizing evenly spaced 20 watt halogen lamps, it takes minutes to install and provides true color rendition. Also, serves as excellent heat source for reptiles.

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: NORTH CAROLINA: Montgomery Co: 6.8 km S Troy & 8.2 km SW Troy. 11 June 1987. A. L. Braswell. Verified by W. M. Palmer. NCSM 28660 (6 larvae), NCSM 28664 (3 larvae), respectively. New county record, and extends range ca. 47 km ENE of the nearest recorded locality (Braswell & Murdock 1979, Brimleyana 1: 135–139). This species was first found at the site 8.2 km SW Troy by H. M. Wilbur and A. S. Weakley on 18 April 1985. Both sites are natural upland pools on clay hardpans.

Submitted by **ALVIN L. BRASWELL**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611, **HENRY M. WILBUR**, Department of Zoology, Duke University, Durham, North Carolina 27706, & **ALAN S. WEAKLEY**, North Carolina Natural Heritage Program, P. O. Box 27687, Raleigh, North Carolina 27611.

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: NORTH CAROLINA: Richmond Co: 21.7 km WNW Ellerbe. 27 April 1988. A. L. Braswell. Verified by W. M. Palmer. NCSM 29190, larva. New county record; extends range ca. 34 km ESE from a Union County site (Braswell & Murdock 1979, Brimleyana 1: 135–139), and about 26 km SSW from a Montgomery County site (Braswell, et al. 1990, SSAR Herp. Review—this issue). Five breeding sites, all located in the Yadkin/Pee Dee River drainage, are currently known for this species in the Piedmont of North Carolina. Curiously, in North Carolina, *A. talpoideum* continues to be known only from the Mountains and Piedmont, where it appears to occur in widely separated, disjunct populations.

Submitted by **ALVIN L. BRASWELL**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611.

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: SOUTH CAROLINA: Greenville Co: 11.6 km NNW Greenville. 17 March 1982. Kevin P. Quinlan. Verified by Raymond D. Semlitsch. Furman University Zoological Collections (FUZC 545). Second reported population in county and first for Armstrong Creek drainage; 8 km NNW Greenville. 5 February 1989. William R. Teska. Verified by Trip Lamb. Furman University Zoological Collections (FUZC 11088). Same location as that of Murdock & Braswell (1985, SSAR Herp. Review 16: 31) and documents established population at that site.

Submitted by **WILLIAM R. TESKA**, Department of Biology, Furman University, Greenville, South Carolina 29613.

AMBYSTOMA TIGRINUM TIGRINUM (Eastern Tiger Salamander). USA: VIRGINIA: Augusta Co: George Washington National Forest, ca. 18 km SW Waynesboro. 12 May 1987. R. L. Hoffman & K. A. Buhlmann. Verified by J. C. Mitchell & C. A. Pague. CM 118612. New county record (ca. 161 km WNW of the nearest previous locality) and first record outside the Coastal Plain in Virginia; first record for the species in the Ridge and Valley Physiographic Province. Larvae were obtained by dipnetting in breeding ponds on 12 May 1987; some were preserved immediately, three others were maintained alive until metamorphosis occurred (10 July 1987). Breeding adults were photographed (KAB collection), toeclipped, and released at the same ponds on 8 March 1988 and additional adults were observed there on 5 March 1989. Although "out of range" localities for *A. tigrinum* may on occasion result from accidental or intentional introductions (e.g., as discarded fish bait), the probability that the Augusta County population is indigenous is enhanced by the syntopic occurrence of numerous kinds of Coastal Plain plants (Carr 1938, Proc. Va. Acad. Sci. 16: 44; 1940, The New Phytologist 39: 129–132). Occupation of the Shenandoah Valley by *A. tigrinum* during the Pleistocene has been documented for a fossil site ca. 44 km from our locality (Holman 1986, Virginia. Div. Mineral Res. Publ. 75: 39–40).

Submitted by **KURT A. BUHLMANN**, Virginia Natural Heritage Program, 203 Governor Street, Suite 402, Richmond, Virginia 23219, & **RICHARD L. HOFFMAN**, Virginia Museum of Natural History, Martinsville, Virginia 24112.

ANEIDES FERREUS (Clouded Salamander). USA: CALIFORNIA: Humboldt Co: 7.4 km S, 1.6 km W Salyer, 792 m. 3 April 1983. MVZ 181841. 10.5 km E Hoopa, 792 m. 13 December 1982. ANURA

ELEUTHERODACTYLUS JOHNSTONEI (NCN). PANAMA: PROVINCIA DE PANAMA: Distrito de Panamá: Ciudad de Panamá: Correguimiento de San Francisco: Avenida 3C Sur, No. 14. 27 June 1989. R. Ibáñez D. Specimen and sonogram verified by R. I. Crombie. USNM 292592. New country record; an exotic species; probably introduced from the southern part its range (R. I. Crombie, pers. comm.). According to Hardy & Harris (1979, Bull. Maryland Herp. Soc. 15: 124–133), *E. johnstonei* originated somewhere in the eastern Caribbean, and it has been introduced into several Caribbean Islands and Bermuda, as well as mainland Guyana and Venezuela. This frog is common in gardens of Altos del Golf and Loma Alegre, residential areas of the Ciudad de Panamá, and probably was introduced along with exotic plants between the years 1984–1987.

RANA PRETIOSA (Spotted Frog) USA: IDAHO: Boundary Co: roadside backwater of Long Canyon Creek (Sec. 25, T65N, R2W). 7 May 1989. P. V. Lindeman. Verified by R. L. Wallace. University of Idaho Lower Vertebrate Collection (IA 646–1 & IA 646–2). New county record (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest, Univ. Press Idaho, 332 pp.).

Submitted by **PETER V. LINDEMAN**, Division of Biological Sciences & Related Technologies, Madisonville Community College, College Drive, Madisonville, Kentucky 42431.

SMILISCA BAUDINII (Mexican Treefrog). MEXICO: NAYARIT: Isla María Madre, El Zacatal (Tres Marias Islands). 20 October 1986. G. Casas-Andreu. (IBH 6338–1 to 6338–2, adults; IBH 6347 tadpoles). First record of this species from Tres Marias Islands (Zweifel 1960, Bull. American Mus. Nat. Hist. 199: 77–128; McDiarmid et al. 1976, Los Angeles Co. Nat. Hist. Mus. Contr. Sci. 275: 1–17).

Submitted by **GUSTAVO CASAS-ANDREU**, Colección Herpetológica, Instituto de Biología, UNAM, Apartado 70–153, México, D. F. 04510, México. ●

TESTUDINES

CHELYDRA SERPENTINA (Snapping Turtle). USA: WISCONSIN: Door Co: Nasewaupee Township near Potawatomi State Park (Sec. 22, T28N, R25E). 11 August 1989. Dreux J. Watermolen. Verified by P. A. Cochran. University of Wisconsin Green Bay Richter Collection (UWGB 393). Two unhatched eggs, one egg that was cut open, one hatchling turtle. New county record (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Pub. Mus. 205 pp.).

Submitted by **DREUX J. WATERMOLEN**, Division of Natural Sciences, St. Norbert College, De Pere, Wisconsin 54115.

CHELYDRA SERPENTINA (Snapping Turtle). USA: WISCONSIN: Manitowoc Co: East Twin River, down-stream from spillway in Mishicot (Sec. 5, T20N, R24E). 22 May 1989. P. A. Cochran & J. Marks. Verified by Robert Henderson. MPM Color Slide P 234. First published county record (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Pub. Mus. 205 pp.), although a novel set in Manitowoc County (Vukelich, 1962, Fisherman's Beach, St. Martin's Press, New York, 186 pp.) includes an encounter with this species.

Submitted by **P. A. COCHRAN & J. MARKS**, Division of Natural Sciences, St. Norbert College, De Pere, Wisconsin 54115.

CHRYSEMYS PICTA BELLII (Western Painted Turtle) USA: IDAHO: Boundary Co: near backwater of Deep Creek, adjacent to southern boundary of Kootenai National Wildlife Refuge (Sec. 36, T62N, R1W). 6 May 1989. P.V. Lindeman. University of Idaho Lower Vertebrate Collection (IR 439–1). Shell fragments comprising approximately 75% of the carapace and plastron of a large adult found, and several individuals seen basking on a log nearby. Kootenai Co: Rainy Hill Road, near Medicine Lake (Sec. 27, T48N, R2W). 11 October 1987. P.V. Lindeman. IR 386–1. Both verified by R. L.

Wallace. Both new county records (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest, Univ. Press Idaho, 332 pp.).

Submitted by **PETER V. LINDEMAN**, Division of Biological Sciences & Related Technologies, Madisonville Community College, College Drive, Madisonville, Kentucky 42431.

CLEMMYS GUTTATA (Spotted Turtle). USA: GEORGIA: Sumter Co: 6 km S Americus. 6 March 1989. Bob Herrington. Georgia Southwestern College Vertebrate Collection (#1651). New county record that extends the range 37 km NW in the Muckalee Creek drainage, and substantiates the presence of a small population in this drainage (Camp & Powder, 1980, SSAR Herp. Review 11: 80).

Submitted by **BOB HERRINGTON**, Department of Biology, Georgia Southwestern College, Americus, Georgia 31709.

CLEMMYS INSCULPTA (Wood Turtle). USA: MICHIGAN: Baraga Co: below Prickett Dam on Sturgeon River (Sec. 14, T50N, R34W). 21 August 1986. Jeff S. Davis. Northern Michigan University Zoological Collection (NMZ 50). Adult male shell and skeletal remains. New county record. Extends range ca. 40 km east of nearest record in Ontonagon County (NMZ 51; Flintsteel River, Sec. 18, T51N, R39N) and Ontonagon County record reported by Johnson (1965, A Zoogeographical Analysis of the Herpetofauna in Northern Michigan and Adjacent Isle Royale, Master's Thesis, Michigan State University, 90 pp.); Houghton Co: Sturgeon River SW U. S. Rt. 41 (Sec. 16, T53N, R33W). 20 June 1987. Jeff S. Davis. Northern Michigan University Zoological Collection (NMZ 52, NMZ 53; photographs only). These two individuals were weighed, measured, blood sampled, marked, photographed and are currently being used in a captive breeding project under the direction of J. S. Davis. New county record. Extends range ca. 56 km NE of nearest record in Baraga County reported above.

Submitted by **JEFFREY S. DAVIS & J. KIRWIN WERNER**, Department of Biology, Northern Michigan University, Marquette, Michigan 49855.

GRAPTEMYS KOHNII (Mississippi Map Turtle). USA: TEXAS: Parker Co: ca. 0.4 km S Interstate 20 bridge over Brazos River. 16 September 1989. Michael B. Harvey & Michael E. Dorcas. Verified by J. A. Campbell. UTA R-25948. Better defines northwest extension of range. (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas, 434 pp.).

Submitted by **MICHAEL E. DORCAS & MICHAEL B. HARVEY**, Department of Biology, University of Texas at Arlington, Texas 76109.

GRAPTEMYS PULCHRA (Alabama Map Turtle). USA: GEORGIA: Murray Co: Conasauga River at St. Rt. 2 (34° 55' 17" N, 84° 50' 30" W). 15 August 1989. S. Santhuff & S. Lay. Fernbank Science Center (FSC R89–101). Whitfield/Murray Co. line: Conasauga River (34° 40' 27" N, 84° 56' 34" W). 14 July 1989. S. Santhuff & D. Wasson. FSC R89–103. Whitfield Co: 8.5 km. S. of St. Rt. 52 on Conasauga River (34° 44' 19" N, 84° 52' 39" W). 4 August 1989. S. Santhuff & D. Ryan. FSC 39–102. Gordon Co: two localities, one on the Conasauga River (34° 32' 35" N, 84° 54' 07" W) and one on the Oostanaula River (34° 33' 08" N, 84° 54' 59" W). S. Santhuff & M. Smith. FSC R89–104–5. Previously there was only one known specimen from Georgia (Harris et al. 1982, SSAR Herp. Review 13: 24). These specimens verify the species in the state and establish two new county records (Gordon & Murray) for *G. pulchra*. The specimens extend the turtle's known range northeast 12.6 km on the Conasauga River to within 7.5 km of the Tennessee state line.

Submitted by **STEVEN D. SANTHUFF**, 6531 Gray Hawk Way, Stone Mountain, Georgia 30087 & **LAWRENCE A. WILSON**, Fernbank Science Center, 156 Heaton Park Drive, Atlanta, Georgia 30307.

HYDROMEDUSA TECTIFERA (South American Snakeneck Turtle). ARGENTINA: MISIONES: Departamento L.N. Alem: Colonia Taranco, Cerro Azul (27° 38' S, 55° 29' W). 12 June 1987. A. Morgenstern & E. Richard. FML Chelonii 027. First record for the Department. The species was previously recorded from Misiones departments Iguazú and General Manuel Belgreano (Waller & Chebez, 1987, Hist. Nat. 7(5): 53–59).

Submitted by **ENRIQUE RICHARD**, Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000-Tucumán, Argentina, & **ARMANDO MORGENSTERN**, Facultad de Ciencias Naturales, Instituto Miguel Lillo, Miguel Lillo 201, 4000-Tucumán, Argentina.

Computerize Your Field Notes and Collections

GECKO is a computer program for managing field notes and collections.

GECKO will allow you to:

Record genus, species, subspecies, number, locality, county, state, collector or observer, collection number and comments. Family, order and class are entered automatically.

Extract data for viewing, editing or printing by any combination of the above, e.g. iguanid lizard localities for Inyo Co, CA or all herps seen in Texas from June through August.

List data by order of entry, by date or phylogenetically.

Copy selected records to files for use with spreadsheets, word processors or data base programs.

Count number of species for all or part of the data base, e.g. number of species for 1988 or number of species of *Hyla*.

GECKO is very powerful, yet uses simple screen menus. It incorporates a master species list and is sold with your choice of the U.S. and Canadian list of herps, birds or mammals. Other species lists can be purchased separately and merged into a comprehensive list of terrestrial vertebrates. Lists can be easily edited to accommodate taxonomic changes or new species.

GECKO runs on IBM PCs and compatibles with 320K RAM and DOS 2.0 or later. $75 + $3 shipping. California residents add 6% tax. Please specify species list to be included. Additional lists are $25 each. Similar programs which use common names are available for all terrestrial vertebrates.

Sandpiper Software 153 Michele Circle, Novato, CA 94947

KINOSTERNON FLAVESCENS FLAVESCENS (Yellow Mud Turtle). USA: MISSOURI: Ray Co: Hardin, DOR on Mo. Rt. 10, 0.3 km E of Co. Road DD (Sec. 33, T52N, R26W). 16 July 1989. F. E. Blake & D. D. Smith. Verified by R. Powell. KU 211303. This is the first recorded locality in west-central Missouri, and is ca. 218 km from the Lewis County record and 236 km from the Jasper County record in the NE and SW corners of the state, respectively (Johnson 1987, The Amphibians and Reptiles of Missouri, Missouri Dept. Conserv. Publ., 368 pp.).

Submitted by **DONALD D. SMITH**, Division of Allergy & Rheumatology, University of Kansas Medical Center, 39th Street & Rainbow Boulevard, Kansas City, Kansas 66103, & **FRANCIS E. BLAKE**, 1815 North Kendall Road, Independence, Missouri 64058.

PHRYNOPS GEOFFROANUS TUBEROSUS (Geoffroy's Sideneck Turtle). GUYANA: POTARO-SIPA-RUNI (REGION 8): Kato, 0.5 km N airstrip, 760 m. 16 March 1989. Robert P. Reynolds. Verified by Carl H. Ernst. USNM 291154–56. Two juveniles and one adult collected in 2x3 m sedge-filled pool at spring-head that ultimately flows ca. 0.5 km north to the Chiung River. First unequivocal Guyana records of *P. geoffroanus* (Pritchard & Trebbau, 1984, Turtles of Venezuela, SSAR Contrib. Herp. 2: 375 pp. + 2 appendices). Peters (1870, Ueber *Platemys tuberosa*, eine neue Art von Schildkroten aus British-Guiana, Monatsber. Akad. Wiss. Berlin, 1870: 313) reported the type locality as "Cotingaflusse am Roraimagebirge in Britishguiana." Pritchard & Trebbau (1984) noted that the Cotinga River drains south from mount Roraima entirely within Brazilian territory, and suggested that the type may not constitute a valid Guyanese record. Present records extend range ca. 120 km SE of the type locality at the Cotinga River near Mount Roraima (Brazil).

Submitted by **ROBERT P. REYNOLDS**, U.S. Fish and Wildlife Service, Biological Survey Section, National Museum of Natural History, Washington, D.C. 20560. ●

LACERTILIA

CRYPTOBLEPHARUS POECILOPLEURUS (Snake-eyed Skink). FRENCH POLYNESIA: Tuamotu Archipelago, Nukutipipi Atoll. November 1988. B. & F. Salvat. MNHN 1989–29 & 1989–36. First record for Nukutipipi Atoll. Known before from the Archipelago (Ineich & Blanc 1988, Atoll Res. Bull. 318: 1–75).

Submitted by **IVAN INEICH**, Centre de l'Environnement, Antenne Muséum/E.P.H.E., B.P. 1013, Papetoai, Moorea, French Polynesia, & Muséum National d'Histoire Naturelle, Laboratoire des Reptiles et Amphibiens, 25 Rue Cuvier, 75005 Paris, France.

EMOIA PHEONURA (NCN). FRENCH POLYNESIA: Tuamotu Archipelago, Nukutipipi Atoll. November 1988 & July 1989. B. & F. Salvat, J. A. Madec. MNHN 1989–27 & 28, 1989–32 to 35, 1989–3041 to 3043. First record for Nukutipipi Atoll. Known before from the Archipelago (Ineich & Blanc 1988, Atoll Res. Bull. 318: 1–75).

Submitted by **IVAN INEICH**, Centre de l'Environnement, Antenne Muséum/E.P.H.E., B.P. 1013, Papetoai, Moorea, French Polynesia & Muséum National d'Histoire Naturelle, Laboratoire des Reptiles et Amphibiens, 25 rue Cuvier, 75005 Paris, France.

EUMECES EGREGIUS (Mole Skink) USA: GEORGIA: Columbia Co: vacant lot in Augusta. 19 April 1987. Tony Mills. Verified by J. Whitfield Gibbons. SSM 12400. Specimen was discovered under roofing metal the collector had placed several years before as a refuge for small vertebrates. On 17 March 1988 another *E. egregius* was collected under the same piece of roofing material and later released by Tony Mills and Matt Whiles. The Mole Skink has been collected in adjacent Richmond County (Neill 1940, Copeia 4: 266), but these specimens represent a new county record. Over the years the collecting area has received a great deal of developmental pressure, reducing it into an isolated vacant lot. Since the latest specimen was collected, this island of habitat has been totally cleared and no suitable substitute seems to be available nearby. The habitat was ca. two hectares and was characterized by vegetation similar to that described by Mount (1963, Amer. Midl. Nat. 70: 356–385.) These specimens represent the most northeasterly record for this species.

Submitted by **TONY MILLS**, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29801.

EUMECES GILBERTI RUBRICAUDATUS (Western Redtail Skink). USA: NEVADA: Nye Co: Nevada Test Site: southern foothills of Pahute Mesa on the eastern edge of Forty-mile Canyon, ca. 1525 m. 30 May 1979. O. L. Haworth. Verified by W. W. Tanner. BYU 37051. Two additional specimens have been collected on top of Pahute Mesa: Nevada Test Site: Trail Ridge, 1600 m NNE of junction of Pahute Mesa & 20–03 roads, 1806 m. 2 June 1982. M. Sauls. E. G. & G. Energy Measurements Inc. (E.G. & G. 82–1). Nevada Test Site: 0.3 km N jct. of Pahute Mesa Road & Buckboard Mesa Road, 1914 m. 13 September 1988. P. A. Medica. Verified by W. W. Tanner. BYU 39708. The above three records are the first reported specimens for the Nevada Test Site. They extend the range ca. 130 km WNW of the Sheep Range (Hardy 1948, Herpetologica 4: 165); ca. 135 km NW of Lee Canyon, Spring Range, (Banta 1962, Herpetologica 18: 129–130); and 65 km NE of Grapevine Peak (Rogers & Fitch 1947, Univ. Calif. Publ. Zool. 48: 169–200).

Submitted by **PHILIP A. MEDICA & ORIN L. HAWORTH**, Reynolds Electrical & Engineering Co., Inc., P. O. Box 495, Mercury, Nevada 89023, & **MARY SAULS KELLY**, E. G. & G. Energy Measurements Inc., Santa Barbara Operations, 130 Robin Hill Road, Goleta, California 93117.

GEHYRA OCEANICA (Oceanic Gecko). FRENCH POLYNESIA: Tuamotu Archipelago, Nukutipipi Atoll. July 1989. B. Salvat & J. A. Madec. MNHN 1989–3034 to 3036. First record for Nukutipipi Atoll. Known before from the Archipelago (Ineich & Blanc, 1988, Atoll Res. Bull. 318: 1–75).

Submitted by **IVAN INEICH**, Centre de l'Environnement, Antenne Muséum/E.P.H.E., B.P. 1013, Papetoai, Moorea, French Polynesia, & Muséum National d'Histoire Naturelle, Laboratoire des Reptiles et Amphibiens, 25 Rue Cuvier, 75005 Paris, France.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko) USA: GEORGIA: Richmond Co: Augusta. 13 November 1989. Rennie Wolfe & Ed Carey. Verified by J. Whitfield Gibbons. Savannah River Ecology Lab (SREL 3340). Approximately twenty animals were discovered beneath debris next to cement loading dock during demolition of the former Mulherin Lumber Company on 13th Street. Juveniles and adults were collected. Eggshell fragments found at the same locality. Collection area completely exposed to outside conditions. The geckos apparently used an area under the cement dock to avoid winter freezing temperatures. It is doubtful that geckos will continue to inhabit this site after demolition since the entire area will be cleared. However, others have been observed ca. 200 meters away at a nearby hospital. Steve Cox (head of building maintenance) noted the lizards' presence since the building's construction in 1987. Juveniles and adults have been observed inside the hospital. The closest recorded locality for *H. turcicus* to Augusta is Lowndes County, Georgia, the first record for the the state (Bechtel 1983, SSAR Herp. Review 14: 27–28). Another population has apparently been established for some time in Eufala, Alabama, just west of the Alabama-Georgia border (T. Lamb, pers. comm.). These localities are ca. 405 and 435 km SW of the Augusta site.

Submitted by **TONY MILLS**, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29801.

LEPIDODACTYLUS LUGUBRIS (Mourning Gecko). FRENCH POLYNESIA: Tuamotu Archipelago, Nukutipipi Atoll. July 1989. B. Salvat & J. A. Madec. MNHN 1989–3033. First record for Nukutipipi Atoll. Known before from

the Archipelago (Ineich & Blanc 1988, Atoll Res. Bull. 318: 1–75).

Submitted by **IVAN INEICH**, Centre de l'Environnement, Antenne Muséum/E.P.H.E., B.P. 1013 Papetoai, Moorea, French Polynesia & Muséum national d'Histoire naturelle, Laboratoire des Reptiles et Amphibiens, 25 Rue Cuvier, 75005 Paris, France.

LIPINIA NOCTUA (Moth Skink). FRENCH POLYNESIA: Tuamotu Archipelago, Nukutipipi Atoll. November 1988 & July 1989. B. & F. Salvat, J. A. Madec. MNHN 1989–30 & 31, 1989–3037 to 3040. First record from Nukutipipi Atoll. Known before from the Archipelago (Ineich & Blanc, 1988, Atoll Res. Bull. 318: 1–75).

Submitted by **IVAN INEICH**, Centre de l'Environnement, Antenne Muséum/E.P.H.E., B.P. 1013, Papetoai, Moorea, French Polynesia, & Muséum National d'Histoire Naturelle, Laboratoire des Reptiles et Amphibiens, 25 Rue Cuvier, 75005 Paris, France.

MABUYA WRIGHTII (NCN). SEYCHELLES ISLANDS: Bird Island, Bird Island Lodge Hotel. Collected one meter from bungalow number four. 4 July 1989. Michéle & Ivan Ineich. MNHN 1989.2566. Only known previously from the granitic Seychelles Islands with large bird colonies. Bird Island is a sandcay with a very large bird colony. Despite search no other specimen of this species was found.

Submitted by **IVAN INEICH**, Centre de l'Environnement, Antenne Muséum/E.P.H.E., B.P. 1013, Papetoai, Moorea, French Polynesia, & Muséum National d'Histoire Naturelle, Laboratoire des Reptiles et Amphibiens, 25 Rue Cuvier, 75005 Paris, France. ●

SERPENTES

ARIZONA ELEGANS (Glossy Snake). USA: NEBRASKA: Thomas Co: US Rt. 83, 4.3 km S Neb. Rt. 2 (Sec. 16, R26W T22N). 9 September 1988. Joseph A. Gubanyi & James Novy. Verified by John D. Lynch. UN 9823. New county record; new species for Sandhills region; extends current range 240 km NNW (Lynch 1985, Trans. Nebraska Acad. Sci. 13: 33–57).

Submitted by **JOSEPH A. GUBANYI**, Department of Biology, Concordia College, Seward, Nebraska 68434.

DRYMARCHON CORAIS RUBIDUS (Mexican Indigo Snake). MÉXICO: SONORA: Tónichi, 172 km SE Hermosillo. 1 May 1989. Adrian Quijada, Valerio Parra, & Reyna Castillo. UANL 3705. Extends distribution 185 km NE of Alamos, Sonora (McCranie, 1980, Cat. American Amph. Rept. 267.1–267.3).

Submitted by **ADRIAN QUIJADA-MASCAREÑAS, VALERIO PARRA, & REYNA CASTILLO**, Escuela Superior de Ecología, CESUES, A. P. A-112, Hermosillo, Sonora, México.

ELAPHE VULPINA (Fox Snake). USA: WISCONSIN: Manitowoc Co: St. Rt. 147, 2 km NW Mishicot (Sec. 35, T21N, R23E). 29 May 1989. P. A. Cochran & A. G. Cochran. Verified by Robert Henderson. MPM 23448. One of two roadkilled examples observed that day in Manitowoc County. First published county record (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin, Milwaukee Pub. Mus., 205 pp.).

Submitted by **P. A. COCHRAN**, Division of Natural Sciences, St. Norbert College, De Pere, Wisconsin 54115.

GERARDA PREVOSTIANA (Gerard's Water Snake). PHILIPPINES: Palawan Island, 35 km NE Brooke's Point at town of Labog (09° 03' N, 118° 3' E). 1 April 1987. David K. Dorman. UF 69099. MALAYSIA: SARAWAK: First Division, 15 km N Kuching, Kampong Santubong (01° 43' N, 110° 19' E). 10 March 1988. Kurt Auffenberg. UF 72991. Verified by Walter Auffenberg. Type locality is "Manila" (Eydoux, F. & P. Gervais 1837. Mag. Zool. Guerin, Paris 3: 1–10) but holotype is missing. A specimen from the Philippines exists (ANSP 5090), but this record has been questioned (Gyi, 1970, Univ. Kansas Publ. Mus. Nat. Hist. 20: 47–223). Known from coasts of India, Sri Lanka, Burma, Thailand, and peninsular Malaysia (Perak). These two new coastal records increase the likelihood that the original type locality was correct and extend the verified range eastward over 1000 miles (Thailand to Palawan).

Submitted by **DAVID L. AUTH, KURT AUFFENBERG, & DAVID K. DORMAN**, Department of Natural Sciences, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611.

NERODIA RHOMBIFER (Diamondback Water Snake). USA: TEXAS: Rains Co: 13 km W Emory on FM Road 35. 26 August 1989. Tony Dunn & Ira Couch. Verified by J. A. Campbell. UTA R-25947. Fills gap between Van Zandt and Hopkins counties. (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M University Press, College Station, Texas, 434 pp.).

Submitted by **MICHAEL E. DORCAS & MICHAEL B. HARVEY**, Department of Biology, University of Texas at Arlington, Texas 76109.

PELAMIS PLATURUS (Yellowbelly Sea Snake). MEXICO: NAYARIT: 9.2 km NE of Isabela Island, Peñascos Las Monas. 28 May 1981. Omar Calvcario. IBH 4328. This record fits within the general distribution of the species in the Pacific of the Americas. Nevertheless, it is the first record from the surroundings of Isabela Island (Pickwell & Culotta. 1980. Cat American Amphib. Rept. 255.1–255.4).

Submitted by **GUSTAVO CASAS-ANDREU**, Colección Herpetológica, Instituto de Biología, UNAM, A. P. 70–153, México, D.F. 04510, Mexico.

PITUOPHIS MELANOLEUCUS DESERTICOLA (Great Basin Gopher Snake). USA: COLORADO: Routt Co: 13 km N Steamboat Springs. June 1983. J. J. Roth. UCM 56041; 1.5 km N Milner. September 1987. J. J. Roth. UCM 56044. New county records extending known range ca. 135 km E of nearest previous record in northwestern Colorado (Hammerson 1982, Amphibians and Reptiles in Colorado, Colorado Div. of Wildlife).

Submitted by **JAN J. ROTH**, Rimrock Taxidermy, 552 Russell Street, Craig, Colorado 81625, & **HOBART M. SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). USA: FLORIDA: Monroe Co: Old Town, Key West. 7 September 1987. R. W. Ehrig. Verified by J. Rosado & V. Wallach. MCZ 172619. New county record (Wilson & Porras 1983, The Ecological Impact of Man on the South Florida Herpetofauna, Univ. Kansas Mus. Nat. Hist. Spec. Pub. No. 9, 89 pp.). Additional individuals seen; one now in captivity with author.

Submitted by **ROBERT W. EHRIG**, Route 3, Box 328, Big Pine Key, Florida 33043.

REGINA GRAHAMII (Graham's Crayfish Snake). USA: ARKANSAS: Woodruff Co: 4.2 km SW Hunter (Sec. 22, T5N, R1W). 3 June 1986. W. W. Byrd, E. L. Hanebrink & Charles Files. Arkansas State University Museum of Zoology (ASUMZ 10742 & 10743). New county record (Dowling 1957, Occ. Pap. Univ. Arkansas Mus. 3: 1–51).

Submitted by **WILLIAM W. BYRD, EARL L. HANEBRINK, & CHARLES FILES**, Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467.

RHADINAEA FLAVILATA (Pine Woods Snake). USA: NORTH CAROLINA: Beaufort Co: 4.5 km WNW Pamlico Beach. 2 May 1990. J. C. Beane & S. L. Alford. Verified by W. M. Palmer. NCSM 30165. Adult male taken under board at trash dump. New county record; extends range on mainland north of Pamlico River and ca. 35 km ENE of nearest record in Craven County (Palmer & Stephan 1972, SSAR Herp. Review 4: 171). Fills part of gap between

northern-most mainland populations and presumed disjunct populations on Outer Banks of Dare County (Braswell 1989, ASB Bull. 35: 199–217).

Submitted by **JEFFREY C. BEANE**, North Carolina State Museum of Natural Sciences, Box 27647, Raleigh, North Carolina 27611.

SISTRURUS CATENATUS EDWARDSII (Desert Massasauga). USA: ARIZONA: Cochise Co: Rt. 666, 13.5 km north of U. S. Rt. 30 near Douglas. 22 August 1988. T. Sinclair & T. Snell. Verified by Harry W. Greene. MVZ 209129. First record from this far west of the Chiricahua Mountains since 30 August 1957, when a single specimen (AMNH 81799) was collected by Carl Alimonti. An earlier specimen was collected by William Woodin on 9 August 1950.

Submitted by **TOM SINCLAIR**, 549 Dowling Blvd, San Leandro, California 94577, & **TONY SNELL**, P. O. Box 136, Portal, Arizona 85632.

BOOK REVIEWS

Salamanders of Ohio, edited by Ralph A. Pfingsten and Floyd L. Downs. 1989. College of Biological Sciences, The Ohio State University, Columbus, Ohio, USA. i-xx + 315 pp. + 29 plates. $30.00.

When I arrived in early January, 1974, at the Museum of Zoology, The University of Michigan to assume the curatorial position long held by Charles F. Walker, I was surprised and mildly amused to learn that Charles had not yet cleared his office and moved into his emeritus headquarters down the hallway. This was of interest to me as I had been assigned his office space. The solution to the problem was to pile my boxes of books and other paraphernalia in the hallway and spend the next few days helping Charles move into his new office. This proved to be a pleasant way to get to know Charles, and it was my first introduction to the then pending volume on the "Salamanders of Ohio."

Charles had earlier published the "Frogs of Ohio" and had been working on the companion salamander volume for some time. The office I was soon to occupy was crammed full of bottles of salamanders from Ohio, most of which were on loan from various Ohio museums. As we moved these salamanders Charles would occasionally point out some "difficult" specimens. Of particular concern to Charles were numerous specimens of *Ambystoma* from northern Ohio, including some of the Lake Erie Islands, which he believed to be hybrids. He also suspected that some of them might be triploid and that some might represent all-female species. Such problems had

delayed completion of the "Salamanders of Ohio," but Charles was optimistic that retirement would free him to finish his two pet projects. The first was the salamander book and the second a revised edition of James Peters' (1952) list of types in the herpetology collections of the Museum of Zoology.

Within a few years, however, it became painfully obvious that Charles would not be able to finish the salamander book. Being a careful, methodical worker, Charles was haunted by the lack of answers to various questions concerning the salamander fauna of Ohio, and, by his own admisison, writing was a very slow and vexatious process for him. Charles had mixed feelings, but mostly a sense of relief when a committee of salamander specialists headed by Ralph Pfingsten and Floyd L. Downs was formed to produce the "Salamanders of Ohio." Relieved of this burden, Charles turned his attention to the UMMZ type lists and had nearly completed this work when he died in 1979. The amphibian and reptile type lists were later published by Arnold Kluge. Thus, although Charles never saw his two "retirement projects" come to fruition, both tasks have been completed by others.

The "Salamanders of Ohio," appropriately dedicated to Charles Walker, is an outstanding, scholarly volume, and one of which I am sure Charles would have approved. It was published as the second issue of Volume 7 of the Bulletin of the Ohio Biological Survey, New Series. The soft-cover book has an attractive white cover with a painting by David Dennis of two spotted salamanders among a field of spermatophores deposited on maple leaves on a pond bottom. Fifteen authors contributed to the book, which, aside from dedication and introductory pages, includes sections on the geology and physiography of Ohio, illustrated keys to both the larval and adult salamanders of Ohio, species accounts, a glossary, an extensive bibliography, and a subject and species index. At the end of the book there are 29 color plates consisting of both photographs and paintings.

The authors recognize 25 species in five families and ten genera occurring within the state of Ohio. The species accounts are arranged by family, and a brief family account is provided; there are no generic accounts. Each species account begins with the scientific name followed by the name of the original describer; synonymies are not given. The common name, taken from Collins et al. (1982) and Banks et al. (1987), is then listed, and this is followed by a black and white photograph. The text of the species accounts is arranged in the following order of headings: Description, Size and Sexual Dimorphism, Distribution, Habits and Life History, Behavior, Remarks, and Locality Records.

Each account contains a pair of distribution maps. Localities within Ohio are indicated by symbols placed on a map of Ohio showing counties and major rivers. Pre-1950 and post-1950 records are indicated with different symbols. A few maps include enlarged sections of the Lake Erie Islands to show species that occur on some of these islands. On the same page is a smaller map of the United States, parts of Canada, and northern Mexico (state, department, and province boundaries not indicated) showing the total range of the species by shading. The list of locality records is arranged by county, and the museum acronym for each record is given. More than 40,000 specimens were used to compile the distribution maps, and the editors wisely chose not to list the specimen identification numbers.

The species accounts are well written, highly detailed, and surprisingly uniform in style, considering that they were written by various authors. The account of the small-mouthed salamander, *Ambystoma texanum*, written by Floyd Downs, is particularly informative. Downs skillfully summarizes what is known about this species and cogently analyzes various problems. One of these is the hybrid complex of *Ambystoma* in northern Ohio, which in some cases includes *A. texanum* as one of the two or three parental species. Another is the existence of a stream-breeding type of *A. texanum* that occurs in southwestern Ohio, southeastern Indiana, and central Kentucky. This form subsequently was named *Ambystoma barbouri* by Kraus and Petranka (1989), and it is the only member of the Ohio salamander fauna not specifically listed in the book.

The authors give reasons for excluding *Eurycea cirrigera* and *Plethodon dorsalis* from the state list, and they follow Bogart et al. (1987) in not recognizing *Ambystoma nothagenes* as a valid species. The problem concerning the number of species of the *Plethodon glutinosus* complex in Ohio is understandably left unresolved, although it is suggested that *P. kentucki* may occur in southern Ohio.

The black and white photographs are of variable quality, some being too dark or with backgrounds that obscure the outline and pattern of the salamander. But the color plates, which include photographs of general habitats and salamanders and paintings of salamanders, are of uniformly high quality. Of particular value are the numerous color photographs of larve and metamorphosing individuals.

The "Salamanders of Ohio" is an outstanding contribution to American herpetology. Above all it must be emphasized that the book is much more than just a guide to the identification of the salamanders of Ohio. The species accounts are full of information on ecology, distribution, variation, and life history that will be of interest to both amateur and professional herpetologists as well as to conservationists and wildlife managers. Not only is previous literature thoroughly reviewed, but much new information is presented so that the book is a primary source of information on salamanders. Considering the subject matter, outstanding quality, and depth of coverage, the "Salamanders of Ohio" can be compared only to Sherman C. Bishop's (1941) classic study of "The Salamanders of New York." These two books set the standards for which others should strive.

Digest for the Successful Terrarium, by Richard D. Bartlett. 1989. Tetra Press, Tetra Sales, USA, Morris Plains, NJ. 79 pp. ISBN: 3-89356-035-1. Available from: Lewis Books, P.O. Box 41137, Sharonville, OH 45241. $4.99 + $2.00 shipping and handling.

The title of this book is very descriptive of its contents. It is a condensed, digested summary of the vast knowledge and personal experience that its author, Richard Bartlett, has had with the captive maintanance of reptiles and amphibians. He has squeezed an enormous amount of basic care information into a mere 79 pages.

The book begins with a short introduction which is more informative and useful than the introductions of many other books. It is the only place that captive propagation is mentioned to any extent, in the whole publication. The introduction is followed by a one-page glossary of terms which is quite adequate for a book of this nature.

Following the glossary are the five major chapters which collectively make up the heart of the book and which contain its real substance. These chapters are organized, not on the basis of the taxonomic relationships of the terrarium inhabitants, but on the conditions of life in the terraria. Thus, there is a chapter on aquatic terraria, one on turtle aquaria, one on semi-aquatic terraria, one on dry-land terraria, and a chapter entitled "Homes for Herptiles," which deals with the maintenance of reptiles in cages as opposed to true terraria. The chapter on dry-land terraria is sub-divided into a section on woodland terraria and a section on desert terraria.

Each of these five chapters is organized in a similar fashion. Each one begins with an introductory section that explains how to set up an aquarium or terrarium of the type to which that chapter is devoted. It includes such information as the kinds of enclosures that can be used, choice of substrate, extent and depth of water, ratio of water area to land area, quality and intensity of lighting, and even some suggestions as to the kinds of

plants to be included, where applicable.

After this introductory section, each chapter (except for the one on turtle aquaria), discusses, under separate headings, those taxa of common reptiles and amphibians that are adapted to living in a terrarium of that type. Frequently, several species or even several genera are discussed together because their requirements are identical or similar. This was obviously necessary to conserve space in a book of such restricted size. The discussions include all of the basic maintenance requirements such as, but not restricted to, food preferences, temperature range, maximum size to be anticipated, space needs, and special information about certain groups, such as pointing out those with particularly nasty temperaments. The discussions vary in length, apparently based on what the author felt was the minimum amount of information needed for successful husbandry of that group or individual species.

Following these main chapters, there is a very short chapter on outdoor pools or "ferneries," and a slightly longer chapter on diet supplements, health aids, and other products produced by Tetra-Terrafauna®, the publishers of the book. Since they published it, it is only natural that they should want to feature their products in the book, but numerous color photographs of bottles, cans, and packages of their products seems excessive.

There is also a table entitled: "Care Guide to 25 Common Reptiles." This is a fact-filled table which lists the requirements of 25 species of lizards, snakes, and turtles. For each species it lists terrarium specifications, heat, diet and care, diet supplements, and special comments. Again, understandably, products of the publisher are mentioned prominently, but the table is still an invaluable guide for the beginning terrarist. It is unfortunate that space did not allow for expansion of this table and the inclusion of a similar table for amphibians. The table is followed by a list of publications for additional reading, and the book ends with a comprehensive index.

The book is beautifully illustrated throughout with color photographs, most by the author, but with some by John Tashjian. There are also line drawings, all but two of which were done by Patricia Bartlett.

To whom would I recommend this book? Certainly to any beginning terrarists, be they child or adult. They should read it from cover to cover before acquiring any of the equipment or appointments for their proposed terrarium, and certainly before acquiring any living animals. The book will be a great help in selecting the proper herps for their particular conditions. The book will also be a great help to terrarists who have concentrated on one group of herps but who are thinking of expanding into another group with which they are less familiar. For example, a turtle specialist would do well to read this book before expanding into lizards or salamanders. It could well prevent disappointments and unpleasant surprises for both the terrarist and the herp.

Oklahoma Herpetology: An Annotated Bibliography, by Charles C. Carpenter and James J. Krupa. University of Oklahoma Press, Norman, 1989. vii + 258 pp., $21.95.

With the advent of greatly decreased natural habitat, increased environmental concerns and non-game species funding the publication of a state or regional bibliography is usually anxiously awaited.

This book is divided into a Preface, Introduction, Checklist of Extant Oklahoma Amphibians and Reptiles, Annotated Bibliography, Genus and Key Word Index, and English Name Index.

The Introduction indicates the substantial thought and effort directed toward efficient access to the literature. Each citation is assigned a unique sequence number. If the title of the article fails to convey the article's pertinence, a brief description is typically provided. This is followed by one or more of the following key words: archeology, behavior, bibliography, development, distribution, ecology, economics, evolution, general reference, genetics, health, historical, husbandry, lore, management, morphology, natural history, paleontology, parasitology, physiology, popular, taxonomy, and techniques. The annotation ends with a list of genera appearing in the article.

The systematic annotation may be reduced by the use of collective phrases such as All Caudata when all genera of Oklahoma's salamanders are discussed.

The Annotated Bibliography contains 1,536 citations published between 1823 and 1987 and is an attempt to be all inclusive. It covers extinct and extant forms.

The Genus and Key Word Index coupled with the English Name Index make this contribution extremely useful to both laymen and professionals.

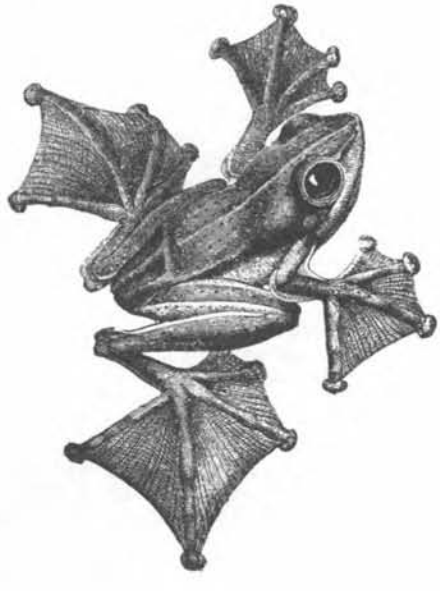
RECENT PUBLICATIONS RECEIVED

Amphibians and Reptiles in the Diets of North American Raptors, by David A. Ross. 1989. Published by the Bureau of Endangered Resources, Wisconsin Department of Natural Resources, P.O. Box 7921, Madison, WI 53707, USA.

This 33-page paper-cover brochure is an annotated bibliography providing references and tables illustrating the occurrence and importance of herptiles to raptors (Falconiformes, Strigiformes, the northern raven, and the loggerhead shrike). Data were compiled from a computer search of over 200 journals and from a review of previous compilations and reviews.

Conversion Factors - SI Units and Many Others, by C.J. Pennycuick. 1988. The University of Chicago Press, 5801 S. Ellis Avenue, Chicago, IL 60637 (originally published by Wiley in 1974). Paper. $5.95. 39 pp. + index.



This book is essentially a reprint of *Handy Matrices,* first published by Edward Arnold in 1974. It provides tables of conversion factors to convert a variety of units into Systeme Internationale units (and some others). Over 2100 factors are listed to convert 21 different physical quantities including energy content, dynamic viscosity, kinematic viscosity, energy flux, metabolic rate, power, work, membrane tension, biomass density, as well as the more common units of time, speed, and length.

Herpetopathologia. Volume 1, No. 1. Editor-in-Chief: G. Matz. This 125-page issue contains papers presented at the Second International Colloquium on the Pathology of Reptiles and Amphibians, held in Nottingham, G.B., on 16-19 September 1984. For subscriptions and information, write to: Presses de l'Université, 5, Boulevard Lavoisier, 49045 ANGERS Cedex, France.

Management of Amphibians, Reptiles, and Small Mammals in North America, Proceedings of the Symposium, July 19-21, 1988, Flagstaff, Arizona. The first 253 pp. of this volume contain 27 articles on various aspects of the management and ecology of amphibians and reptiles, while the following 185 pp. cover the management and ecology of small mammals in 26 articles. Free copies are available (while the supply lasts) from Richard Schneider, USDA Forest Service, Rocky Mountain Forest and Range Experiment Station, 3825 E. Mulberry Street, Craddock Building, Fort Collins, CO 80524. Request Gen. Tech. Rep. RM-166.

Organization of Biological Field Stations—Directory of Members 1989, edited by Joseph F. Merritt and Arlynn K. Adamerovich. 143 pp. Powdermill Biological Station, The Carnegie Museum of Natural History, Rector, PA 15677.

This directory provides information on the 96 biological field stations in North America which are members of the OBFS. Descriptions (1-2 pp. each) are arranged according to geographic regions. Each description gives: Access, Environment, Facilities, Research, Education, and Contact. A Table for the field stations in each region provides information on: Affiliation, Season, Area, Biotic Communities, Facilities, Emphasis.

Herpetological Circular No. 19
Prepublication Announcement

STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES

THIRD EDITION

Joseph T. Collins

This long-awaited third edition lists the scientific names of all currently recognized genera, species, and subspecies of native North American salamanders, frogs & toads, turtles, crocodilians, worm-lizards, lizards, and snakes, as well as the standardized common names for each. Thanks to the previous two editions, over 85% of the state and regional books published about these creatures since 1978 have adopted the standard common names. Common names are now stable for North America, and provide for accuracy of use across the continent by non-biologists. New features in this edition are the inclusion of an appendix of alien (non-native, introduced) species, and the addition of the publication date of description for all taxa. The latter, in conjunction with the name(s) of the describer(s), makes this an invaluable and required reference for every herpetologist interested in the 496 species of amphibians and reptiles found in North America (north of Mexico). An appendix to Hawaiian taxa is included. iv + 41 pages. ISBN 0–916984–21–4

Prepublication price $4.00
After September 30, 1990 $5.00

Orders may be sent to Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056 USA.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** In 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to rteview herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations and photographs. Manuscripts submitted must be typed, double spaced, on 8.5X11 inch paper, and should be sent in duplicate. We encouerge submissions on Macintosh disks, though we can also work with TEXT (ASCII) files submitted on IBM and compatible floppies. **Herpetological Review** is composed on a Macintosh SE using Microsoft Word, which accepts files from several other word processor applications. Format your documents full-page width; we will fit to **HR** format.
Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8X10 inches black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. Herpetological Review will accept commercial advertising. Rates and copy information are available from the advertising manager. Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats. Contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

Society For The Study Of Amphibians And Reptiles

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (4 issues annually), **Herpetological Review** (4 issues annually), and occasional issues of **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1990

Student member.....$25.00*	Sustaining member.....$50.00*
Regular member.....$35.00*	Contributing member.....$75.00*
Institutional subscription.$60.00*	Life member..(see below)...$600.00*

***Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00.

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, draft on a US bank, or by Mastercard or Visa (include account number and expiration date of credit card). Life memberships may be paid in 3 consecutive payments

Subscriptions to Herpetological Review only are available for $12.00 annually. Subscriptions outside of the US require a surcharge of $8.00 for air delivery if airmail is desired. Subscribers to HR only are not members of the Society.

Catalogue of American Amphibians and Reptiles: subscription $15 annually ($3.00 air delivery surcharge if airmail is desired.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

SSAR BUSINESS

SSAR MEETS AT FIRST WORLD CONGRESS OF HERPETOLOGY

The 32nd Annual Meeting of the Society for the Study of Amphibians and Reptiles was held jointly with the First World Congress of Herpetology (FWCH), 11-19 September 1989, on the campus of the University of Kent in Canterbury, United Kingdom. Nearly 1400 persons, representing some 61 countries (see chart), attended this largest and most diverse meeting of herpetologists ever held. The Herpetologists' League and Societas Europaea Herpetologica also met officially at the congress, which was co-hosted by the British Herpetological Society, Fauna and Flora Preservation Society, and the Zoological Society of London. Thirty leading national and international herpetological societies supported the congress as Affiliated Organizations.

The complexities of such a large meeting were enormous—with nearly 50 symposia, workshops, roundtables, exhibits, and other events and with numerous nationalities and languages represented—yet all was effectively managed by Ian R. Swingland, Conference Director, and the UK National Executive. Kraig Adler served as chairman of the Scientific Program Committee. Many features of the congress were familiar to regular attendees of SSAR meetings in North America, since several of the Society's traditional events were incorporated into the program.

World Congress of Herpetology (WCH), the parent organization which initiated and coordinated the First Congress, had its genesis in 1982, on the occasion of SSAR's 25th Annual Meeting in Raleigh, North Carolina, USA (see *Herp Review*, 13:103, 1982). At that anniversary meeting, an *ad hoc* committee made the proposal and representatives of the world's major herpetological societies decided to establish the WCH and elected Kraig Adler, then the President of SSAR, as Secretary-General.

Since that time, the WCH organization has been firmly established, operating funds raised, a constitution written, and meeting plans laid which culminated in the historic inaugural congress last September. Because of the enormous enthusiasm displayed at Canterbury, a Second Congress is now being planned, to be held in four or five years.

Canterbury and the University of Kent

The cathedral city of Canterbury, renowned the world over, is one of Europe's most ancient cities and a settlement has existed on the site since the Stone Age. In 43 A.D. the Romans founded a village of wooden huts there and called it "Durovernum," remains of which can still be seen in the city. The ancient Norman fortress walls, gate towers, and timbered buildings—all clustered around the magnificent cathedral, the Mother Church of England—preserve much of a medieval atmosphere, and congress delegates were able to stroll through the city's narrow, sometimes still cobbled streets. Canterbury also has rich literary associations, being the city of Chaucer, Christopher Marlowe, Charles Dickens, and Somerset Maugham, and it is one of the most visited places in the UK.

The University of Kent, on the other hand, is one of England's newest institutions, founded by Royal Charter in 1965. It occupies a 300-acre campus on a magnificent hillside overlooking the city from the north. Except for the plenary lectures, which were presented at the Marlowe Theater in the city, all other congress events were held on campus. Herpetological activities totally occupied the campus and the official WCH logo was everywhere to be seen. The logo (above) is from Conrad Gessner's *Historia Animalium* (Zürich, 1554), a chameleon perched precariously "out on a limb," as indeed the WCH felt itself to be in its early years!

Registration was conducted in the Senate, a centrally-located building, and most delegates roomed in one of two

Final summary of FWCH delegates, by country. Total attendance included 900 delegates, 316 accompanying persons, and 152 others (honorary officers, special guests, press officials, and others involved in the congress).

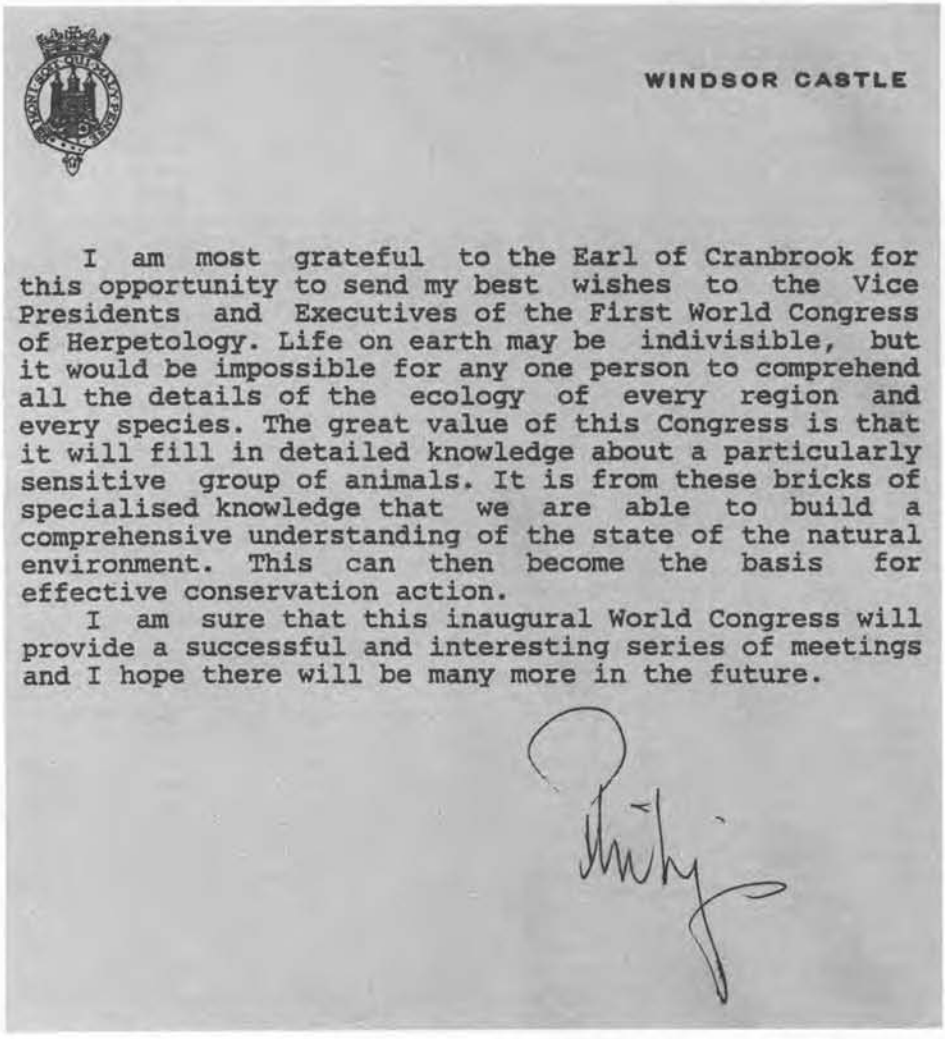
residential colleges (Eliot and Rutherford), each a confusing stereoisomeric image of the other. Each college had a dining hall for meals as well as a bar, in which many lively discussions took place each evening. Two unique brands of beer—"Herpetology Ale" and "Tortoise Bitters"—were brewed specially for the congress, with souvenir bottles conveniently placed in each delegate's room! The self-contained nature of the campus and its pleasant surroundings led to good interactions and camaraderie.

Meeting of SSAR Board of Directors

The SSAR Board met from 1000 to 1630 h on 11 September in the Grimond Lecture Theater (this being one of the shortest board meetings in recent memory!). President Henri Seibert opened the meeting by announcing that Eric Juterbock had agreed to serve as Secretary since James Jacob had to resign the post. Ernest Liner agreed to serve out Juterbock's unexpired board term, since one individual cannot hold two voting positions on the Board of Directors.

Treasurer Douglas Taylor announced that membership was down slightly from last year, probably a result of the dues increase, but SSAR is in better financial shape. Publications Secretary Robert Aldridge announced that more than 60,000 pounds of SSAR publications are now in storage at St. Louis University. Discussion centered on membership drives and publication sales (both anticipated in 1990).



Committee reports were mostly uneventful, although there was some discussion about the role of the Conservation Committee and the current paucity of future meeting sites. After significant and sometimes spirited discussion, a budget of $126,000 was approved for 1990; this included the establishment of an Emergency and Special Projects Fund.

SSAR Business Meeting

President Seibert called the meeting to order at 1930 h on 14 September in Grimond Lecture Theater. Secretary Juterbock reported the highlights of the Board meeting of three days before and Treasurer Taylor reported financial matters (see above). Chairperson James Murphy presented the slate of nominees for the autumn election on behalf of the Nominating Committee. The slate was accepted by unanimous vote. Harold Dundee reported on the 1990 meeting in New Orleans, leaving many to wonder if there would be time for business in between all of the eating and partying!

Martin Rosenberg, on behalf of the Resolutions Committee, presented the following resolutions:

- *"Whereas, James S. Jacob has served as Secretary of SSAR for the past eight years; and*
  Whereas, he has performed said secretarial duties with great efficiency; and
  Whereas, his efforts have greatly enhanced communication between and among officers, committees, and members,
  Therefore, be it resolved that the Society extend its deepest gratitude to James S. Jacob for his many years of service to the Society.
- *"Whereas, Rodolfo Ruibal has served most ably as editor of the Society's scientific journal for seven years; and,*
  Whereas, the Journal of Herpetology *has achieved a high level of preeminence during his tenure as editor; and,*
  Whereas, his efforts have promoted the distribution and sharing of knowledge and discovery among colleagues throughout the world,
  Therefore, be it resolved that the Society recognize Rodolfo Ruibal's invaluable and excellent service to the Society as Editor of the Journal.
- *"Whereas,* Herpetological Circulars *are major publications of the Society; and,*
  Whereas, these publications are highly valued by the herpetological community; and,
  Whereas, Neil Ford has ably served as editor of this series for the past six years;
  Therefore, be it resolved that the SSAR express its gratitude to Neil Ford for bringing six Herpetological Circulars *to publication during his tenure as Editor.*
- *"Whereas, WCH Secretary-General Kraig Adler, FWCH Conference Director Ian R. Swingland, and WCH Treasurer Marinus S. Hoogmoed have devoted thousands of hours over the past half decade toward the organization of this meeting; and,*
  Whereas, this First Congress represents an historic gathering of scientists from 61 countries; and,
  Whereas, this congress has set a high standard of excellence in all respects;
  Therefore, be it resolved that Kraig Adler, Ian R. Swingland and Marinus S. Hoogmoed be duly thanked for their successful efforts.

WINDSOR CASTLE

I am most grateful to the Earl of Cranbrook for this opportunity to send my best wishes to the Vice Presidents and Executives of the First World Congress of Herpetology. Life on earth may be indivisible, but it would be impossible for any one person to comprehend all the details of the ecology of every region and every species. The great value of this Congress is that it will fill in detailed knowledge about a particularly sensitive group of animals. It is from these bricks of specialised knowledge that we are able to build a comprehensive understanding of the state of the natural environment. This can then become the basis for effective conservation action.

I am sure that this inaugural World Congress will provide a successful and interesting series of meetings and I hope there will be many more in the future.

Letter of greetings from His Royal Highness Prince Philip, Duke of Edinburgh, K.G., K.T., the official Patron of the First World Congress of Herpetology.

• *"Whereas, the FWCH has been successfully conducted within the beautiful and historic city of Canterbury; and,*
Whereas, the excellent performances by the English and Scottish dancers and the bagpipe music at the Westgate Gardens provided delegates and guests with an appreciation for the long history and great traditions of the United Kingdom; and,
Whereas, the University of Kent at Canterbury has provided outstanding facilities for the exchange of scientific information; and,
Whereas, the organizers of the FWCH have worked for many years in planning this inaugural world congress;
Therefore, be it resolved that SSAR acknowledge the support and contributions of the following: His Royal Highness Prince Philip; Councillor A. G. Porter, Lord Mayor of the City of Canterbury; David J. E. Ingram, Vice-Chancellor, University of Kent; and the dozens of additional individuals who worked tirelessly to make this meeting a pleasant and effective one."

The resolutions were overwhelmingly accepted by an animated vote of the membership.

Finally, Henri Seibert passed the SSAR gavel, richly carved with herpetological motifs, to President-elect William Brown, who adjourned the meeting at 2020 h.

Student Travel Committee

Several years ago, SSAR, together with the Herpetologists' League and the American Society of Ichthyologists and Herpetologists, established a committee to raise funds to send North American graduate students to the congress. Auctions and other events were conducted to collect funds, including a raffle organized by Ronald Altig and Linda Trueb. The committee (David Cundall, chair; Ronald Altig, John E. Cadle, George C. Gorman, Dale R. Jackson, Linda Trueb, and R. Wayne Van Devender) eventually provided substantial travel grants totalling $4500 to eight persons. SSAR is grateful to the people who successfully organized this program.

Opening Ceremonies

In plenary session at the Marlowe Theater, the First Congress was formally opened by the Secretary-General, Kraig Adler. He noted the historic occasion of herpetology's first truly international congress with its dual themes of science and conservation, and he greeted the delegates on behalf of the WCH Executive Committee.

Ian R. Swingland, Conference Director, extended a welcome on behalf of the Secretariat and the UK National Executive, followed by remarks from David J. E. Ingram, Vice-Chancellor and administrative head of the University of Kent, our official host institution. A group photograph of the delegates was taken that morning on the steps of the Marlowe.

Honorary Officers

At the request of the Secretary-General, the Earl of Cranbrook, a prominent British zoologist, invited a distinguished group of the United Kingdom's leading naturalists and public figures to serve as honorary officers for the First Congress, to demonstrate the widespread support for the congress in Great Britain and to make its planning activities more visible.

H.R.H. Prince Philip, Duke of Edinburgh, K.G., K.T., President of the World Wide Fund for Nature (WWF; formerly called World Wildlife Fund) and a leader in international conservation, consented to be the official Patron of the First Congress. Prof. Angus d'A. Bellairs, the eminent British anatomist and herpetologist, served as Honorary President.

Among the 23 Honorary Vice Presidents were the Most Rev. Robert Runcie, Lord Archbishop of Canterbury and Primate of the Anglican Church; the President of the Zoological Society of London, Sir William Henderson; several leading naturalists and conservationists including, in addition to Lord Cranbrook himself, Sir David Attenborough, Prof. J. L. Cloudsley-Thompson, Mr. Gerald Durrell, Dr. J. F. Deryk Frazer, the Countess of Huntingdon, the Viscount Massereene and Ferrard, the Baroness Nicol, the Hon. Miriam Rothschild, the late Sir Peter Scott, and Sir William Wilkinson; the Director of the British Museum (Nat. Hist.), Dr. R. H. Hedley; Prof. Sir Richard Southwood, Vice-Chancellor of the University of Oxford; Prof. R. J. Berry, President of the Linnean Society of London; and the Rt. Hon. Robin Leigh-Pemberton, Governor of the Bank of England and Lord-Lieutenant of Kent, in which county the congress was held.

Plenary Speakers

In order to highlight some of the most important current areas of research and conservation of amphibians and reptiles, several individuals were invited to present 50-minute plenary lectures at the Marlowe Theater, on the first and last days of the congress. They were introduced by noted personages associated with the congress:

• Carl Gans (USA): *The State of Herpetology.* Introduced by Angus d'A. Bellairs, Honorary President of the First Congress.

• Ilya S. Darevsky (USSR): *Evolution and Ecology of Parthenogenesis.* Introduced by Harold G. Cogger, Chairman of the WCH Constitution Committee.

• Linda R. Maxson (USA): *Molecular Perspectives on Tempo and Pattern in Amphibian Evolution.* Introduced by Marinus Hoogmoed, Treasurer of WCH.

• Russell A. Mittermeier (presenter; USA) and Ian R. Swingland (UK): *International Conservation.* Introduced by the Rt. Hon. the Earl of Cranbrook, Convener of Honorary Officers for the First Congress and President, British Herpetological Society.

• Gerald Durrell (UK): *Conservation and Captivity.* Introduced by Ian R. Swingland, Conference Director of the First Congress.

• Timothy R. Halliday (UK): *Sexual Selection in Amphibians and Reptiles.* Introduced by Richard Fitter, Vice-President, Fauna and Flora Preservation Society.

• Ermi Zhao (China): *Biogeography of the Amphibians and Reptiles of the Islands Along the Chinese Coast.* Introduced by R. J. Berry, President, Linnean Society of London.

• Armand de Ricqlès (France): *Paleoherpetology.* Introduced by Ulrich Joger, General Secretary of Societas Europaea Herpetologica.

• S. Donald Bradshaw (Australia): *Ecophysiology of Desert Reptiles.* Introduced by Roger A. Avery, Chairman, UK National Executive for the First Congress.

• Eric R. Pianka (USA): *Community Ecology.* Introduced by Henri C. Seibert, President of SSAR.

• David B. Wake (USA): *Evolutionary Biology of Salamanders.* Introduced by James R. Dixon, President of Herpetologists' League.

All of these lectures and the Opening and Closing ceremonies were recorded by Q.E.D. Recording Services Ltd. (45

Commemorative poster donated by SSAR to all congress delegates. Copies of this full-color drawing of a box turtle (*Terrapene carolina*) by David M. Dennis are available for purchase from the SSAR Publications Secretary, Robert D. Aldridge (address inside front cover of this issue) at a cost of $8 each postpaid ($5 each for orders of 10 or more). Only about 500 copies of this limited-edition print remain for sale.

Birley Road, London N20 0HB, UK). Complete sets of the 11 tapes are available from Q.E.D. for £60 (approximately $100) postpaid worldwide; payments can be made by VISA, MasterCard, or Amex. Individual cassettes are also available; address inquiries to Q.E.D. The plenary lectures will be published as a single volume; details to be announced later in *Herp Review*. It is also planned to produce a videotape summary of the congress; details will be announced later.

Symposia

A main feature of the congress were 27 symposia, covering an extremely broad range of topics; several symposia will be published. Roger Thorpe served as Symposia Manager. Each event was arranged by two conveners who usually also served as moderators; additional moderators occasionally participated. Most were half-day events, but a few (marked *) covered a full day. In the following listing, all authors of a given paper are given; this list differs from the Program in some instances, but reflects the papers actually presented in Canterbury.

• *Conservation and Management of Species**. Emilio Balletto and Brian Groombridge, conveners. E. H. W. Baard; B. Banks, J. S. Denton, R. J. Flower, and T. J. C. Beebee; Q. M. C. Bloxam and S. J. Tonge; J. A. Campbell; K. Corbett; L. A. Fitzgerald, J. M. Chani, and O. E. Donadio; N. B. Frazer; A. Georges; M. P. Hayes and M. R. Jennings; D. R. Jackson; M. A. R. Khan; E. D. McCoy and H. R. Mushinsky; E. O. Moll; P. Sjögren; D. M. J. Spratt; D. R. Towns.

• *Effects of Environmental Pollution on Herpetofauna*. Arnold S. Cooke and Claes Andrén, conveners. C. Andrén and G. Nilson; R. Beattie; A. S. Cooke; C. P. Cummins; R. J. Hall; M. R. K. Lambert; P. Mohanty-Hejmadi and S. K. Dutta; B. A. Pierce; R. Tyler-Jones, R. C. Beattie, and R. J. Aston.

• *Captive Management of Amphibians and Reptiles*. René E. Honegger and Romulus Whitaker, conveners; Walter Sachsse, moderator. J. L. Behler; L. Durrell, D. Reid, and I. R. Swingland; B. Johnson; H. Rosier; W. Sachsse; D. I. Werner; F. E. Wood and J. R. Wood; E. Zimmermann and H. Zimmermann.

• *Health and Disease*. John E. Cooper and Fredric L. Frye, conveners. P. C. Arena, K. C. Richardson, and L. K. Cullen; J. E. Cooper; F. L. Frye; F. L. Frye and C. Calvert; F. L. Frye and R. S. Funk; T. M. Környei; C. McAllister and S. J. Upton; G. A. Rubël and W. Kuoni; S. E. Solomon and R. Tippett; C. Warwick; R. A. Yates, D. J. Morafka, and J. P. Flanagan; P. Zwart, J. E. Cooper, and R. Ippen. Elkan Memorial Lecturer: F. L. Frye.

• *Sexual Selection and Communication in Amphibians and Reptiles.** Murray J. Littlejohn and Stevan J. Arnold, conveners. A. Arak; D. Crews; M. L. Dyson; H. C. Gerhardt; L. D. Houck; P. M. Narins; N. I. Passmore, P. J. Bishop, and M. L. Dyson; M. J. Ryan, A. S. Rand, and W. Wilczynski; P. Verrell; K. D. Wells and T. L. Taigen; B. D. Woodward.

• *Environmental Sex Determination*. Claude Pieau and Nicholas Mrosovsky, conveners. J. W. Bickham; C. Dournon; M. W. J. Ferguson, D. C. Deeming, P. T. Sharpe, E. Vallely, and A.

The First World Congress of Herpetology was attended by 1368 persons from 61 countries, the largest and most geographically diverse meeting of herpetologists ever held. Delegates assembled at the Marlowe Theater in Canterbury for the plenary sessions.

Watts; N. Mrosovsky; C. Pieau, M. Dorizzi, and G. Desvages; I. R. Swingland.

• *Sensory Processing in Amphibians and Reptiles.* Hans Schneider and John B. Phillips, conveners. A. Elepfandt; G. A. Engbretson; F. Gaillard; T. E. Hetherington; J. B. Phillips; G. H. Rodda; U. Sinsch; D. Vanderstighelen and R. F. Verheyen; W. Walkowiak; W. Wilcyznski.

• *Long Term Studies of Amphibians and Reptiles.* J. Whitfield Gibbons and Henk Strijbosch, conveners. C. Andrén and G. Nilson; K. A. Bjorndal and A. B. Bolten; C. M. Bull; J. D. Congdon; R. C. M. Creemers and H. Strijbosch; A. C. Dunham and K. Overall; J. J. van Gelder; M. Martin; R. S. Oldham; C. J. Reading; J. Reid; M. R. Warburg.

• *Ecology and Behavior of Snakes.** Hubert Saint-Girons and Richard Shine, conveners; R. Duguy, J. W. Gibbons, and P. T. Gregory, moderators. S. J. Arnold; J. P. Baron; A. Bea and F. Brana; W. S. Brown and W. H. Martin; M. B. Charland, A. R. Gibson, P. T. Gregory, and C. R. Peterson; D. Duvall, D. Chiszar, and G. Schuett; N. B. Ford; F. R. Gehlbach; H. W. Greene; H. Heatwole; H. B. Lillywhite and R. W. Henderson; J. M. Macartney, M. B. Charland, and P. T. Gregory; T. Madsen; G. Nilson and C. Andrén; H. Saint Girons, R. Duguy, and G. Naulleau; R. A. Seigel and R. Shine; R. Shine and R. A. Seigel; R. Shine.

• *Ecology and Adaptations in Extreme Environments.* Donald Bradshaw and Leo J. Borkin, conveners. L. J. Borkin, V. A. Cherlin, A. M. Bassarukin, and M. Yu. Maymin; C. James; M. Lemire, R. Vernet, C. Grenot, and J. M. Francaz; H. Mendelssohn and A. Bouskila; K. A. Nagy; H. Saint Girons and S. D. Bradshaw; V. H. Shoemaker; G. K. Snyder and J. R. Nestler; P. C. Withers.

• *Amphibian Community Ecology.* Robert Barbault and Masafumi Matsui, conveners. R. C. Bruce; C. Díaz-Paniagua; N. G. Hairston; R. G. Jaeger; R. F. Inger and H. K. Voris; P. J. Morin; C. A. Toft; H. M. Wilbur.

• *Herpetofaunas: Explorations and Studies.* Ermi Zhao and Donald G. Broadley, conveners. T. C. S. Avila-Pires, F. P. Nascimento, and O. R. da Cunha; J. M. Cei; H. G. Cogger; M. Henzl; M. S. Hoogmoed; R. F. Inger; U. Joger; K. Y. Lue and S. L. Chen; M. Matsui; T. J. Papenfuss and J. R. Macey; J. C. Poynton; C. J. Raxworthy.

• *Evolution and Phylogeny of Frogs.* Raymond F. Laurent and Michael J. Tyler, conveners. R. M. A. Blommers-Schlösser; D. C. Cannatella; A. J. Cardoso; L. S. Ford; D. M. Green; Z. Rocék; B. Sanchíz and C. Martín; G. Wei.

• *The Inter-Relationships of Primitive Tetrapods: The Fossil Evidence.* Leonid P. Tatarinov and Robert Carroll, conveners. J. R. Bolt; J. A. Clack; M. Laurin; A. C. Milner and W. Lindsay; A. R. Milner; A. Panchen and T. Smithson; T. Smithson and A. Panchen; L. P. Tatarinov; D. M. Walsh.

• *Paleoherpetology: Impact on Neoherpetology.* Richard Estes and Borja Sanchíz, conveners; Andrew Milner, moderator. D. C. Cannatella and K. de Queiroz; J. M. Clark; R. Cloutier and L. Trueb; J. A. Holman; P. A. Meylan and E. S. Gaffney; M. A. Norell; G. K. Pregill; J.-C. Rage; Z. Szyndlar and J.-C. Rage.

• *Evolution and Ecology of Island Herpetofaunas.** Thomas Schoener and Ronald Nussbaum, conveners. A. M. Bauer; C. P. Blanc; R. P. Brown and R. S. Thorpe; T. J. Case and D. Bolger; A. S. Gardner; H. Heatwole; I. Ineich; R. B. King; J. B. Losos; A. Malhotra; C. Moritz, T. Case, and D. Bolger; G. K. Pregill; T. W. Schoener; R. S. Thorpe, R. P. Brown, and M. Baez; D. R. Towns; J. W. Wright; W. Wüster and R. S. Thorpe; G. R. Zug.

• *Evolution and Life Histories of Turtles.* Justin D. Congdon and Colin Limpus, conveners. R. J. Brooks, D. A. Galbraith, and M. L. Bobyn; J. D. Congdon; N. B. Frazer; D. A. Galbraith; A. Georges and R. Kennett; J. W. Gibbons; R. Kiester.

• *Molecular Systematics.* Herbert Dessauer and Eviatar Nevo, conveners. B. W. Bowen, A. Meylan, and J. C. Avise; J. E. Cadle; L. D. Densmore, P. S. White, and S. J. Kain; H. C. Dessauer and C. J. Cole; A. Georges and M. Adams; G. Gollmann; U. Joger; R. Lawson; R. W. Marlow; E. Nevo; R. S. Thorpe and A. M. Cumming.

• *Cytogenetics of Amphibians and Reptiles.* Ettore Olmo and Midori Nishioka, conveners; W. Böhme, moderator. E. Arevalo-M., C. A. Porter, and J. W. Sites; M. King; S. Kohno, C. Ikebe, and M. Kuro-o; H. C. Macgregor; G. Mancino; A. Morescalchi; C. Moritz; E. Olmo, E. Odierna, and T. Capriglione; M. Schmid; L. Singh.

• *Modified Sexual Systems: Parthenogenesis and Hybridogenesis.* John W. Wright and Rainer Günther, conveners. R. L. Bezy; L. J. Borkin, R. Günther, Yu. M. Rozanov, and A. E. Vinogradov; W. M. Brown, L. D. Densmore, C. C. Moritz, D. Peccinini-Seale, V. Singh, D. K. Vyas, and J. W. Wright; I. A. Caune and L. J. Borkin; F. D. Danielyan; I. S. Darevsky and T. M. Sokolova; L. D. Densmore, C. C. Moritz, J. W. Wright, and W. M. Brown; J.-D. Graf and M. Polls-Pelaz; R. Günther; R. Günther and J. Plotner; H. Hotz and P. Beerli; F. Kraus and M. M. Miyamoto; L. A. Kupriyanova; B. E. Leuck; L. A. Lowcock; C. Moritz, C. Spolsky, H. Hotz, I. S. Darevsky, L. Kupriyanova, and T. Uzzell; M. Polls-Pelaz and J.-D. Graf; H. G. Tunner and S. Heppich; J. W. Wright, D. Peccinini-Seale, C. Moritz, J. Sites, D. Vyas, and W. Brown.

• *Modern Approaches to Systematics and Phylogeny of Amphibians and Reptiles.** William E. Duellman and Olivier Rieppel, conveners. J. W. Bickham; W. Böhme; W. R. Branch; R. B. Cocroft and M. J. Ryan; W. E. Duellman; U. Joger; A. G. Kluge; J. M. Legler; J. B. Rasmussen; A. G. J. Rhodin; O. Rieppel; L. Trueb and D. C. Cannatella; J. W. Wright.

• *The Biology of the Pipidae.* Richard C. Tinsley and Linda Trueb, conveners. A. M. Báez; H. R. Kobel; R. O. de Sá and D. M. Hillis; R. C. Tinsley; L. Trueb.

• *Energetics of Amphibians and Reptiles.* Warren P. Porter and Raymond B. Huey, conveners. R. A. Avery; A. F. Bennett, B. C. Jayne, and T. Garland, Jr.; K. A. Bjorndal and A. B. Bolten; B. Green; C. Grenot and B. Heulin; K. A. Nagy; J. W. Patterson; W. P. Porter, A. E. Dunham, and J.-P. Chavaz; T. L. Taigen and K. D. Wells; C. R. Tracy.

• *Determinants of Organismal Function.** F. Harvey Pough and Roger S. Seymour, conveners; Robin M. Andrews, Alison Cree, and Dennis R. King, moderators. R. M. Andrews; A. Arillo and E. Balletto; D. Bauwens and R. Van Damme; T. Garland, Jr.; R. G. Jaeger; A. Hailey; D. R. King; K. L. Overall and A. E. Dunham; M. J. Packard and G. C. Packard; J. R. Spotila and M. P. O'Connor.

• *Functional Morphology.* Carl Gans and Jean-Pierre Gasc, conveners. V. Bels; D. Cannatella; C. Gans; J.-P. Gasc; W. Hödl; E. Kochva; J. M. Legler; S. K. Saraswat and C. Gans; B. Shaffer; F. de Vree; P. C. Wainwright; D. Weishample.

• *Reproductive Endocrinology of Amphibians and Reptiles.* Paul Licht and Louis J. Guillette, conveners. J. Gavaud; L. J. Guillette; P. Licht; F. L. Moore; M. C. Moore; R. Pierantoni.

• *Developmental Processes.* Angus d'A. Bellairs and James Hanken, conveners. P. Alberch; S. V. Bryant and D. M. Gardiner; A. C. Burke; P. Collins and F. S. Billett; M. W. J. Ferguson and B. Westergaard; J. Hanken, D. W. Seufert, and C. H. Summers.

Roundtables and Workshops

In order to provide a variety of formats for participation in the congress, roundtables and workshops were arranged to complement symposia and posters. Roundtables allowed informally-organized discussions among experts on given topics, with audience participation, whereas workshops were practical demonstrations and lectures on the latest techniques, sometimes involving hands-on laboratory sessions. Trevor Beebee served as manager. As for symposia, most of these events had two conveners; multiple authorship refers to the form of abstracts published in the Abstracts volume, although only one author may have participated in the event.

roundtables

• *Conservation Needs Achieved.* Keith Corbett, convener. S. Lyster; D. Newman; S. Stewart; D. Stubbs; R. Whitaker.

• *Conservation Biology: The New "Modern Synthesis" and Its Relation to Herpetology.* C. Kenneth Dodd, Jr., Romulus Whitaker, and Gustavo Aguirre, conveners and moderators. K. Berry; C. K. Dodd, Jr.; A. Hailey; B. Magnusson; J. P. Ross; R. Seigel; R. Whitaker and C. K. Dodd, Jr.

• *Optimal Sizes of Eggs and Clutches.* Henry M. Wilbur and Laurie J. Vitt,

conveners. N. B. Ananjeva and S. Shammakov; J. Bernardo; C. M. Bull and I. Williamson; J. D. Congdon; C. P. Cummins; M. L. Crump; K. Y. Lue and K. S. Chuang; L. Schwarzkopf; R. Seigel, R. Shine and L. J. Vitt; B. Sinervo; P. Sjögren; J. Travis.

• *Antipredator Mechanisms.* Edmund D. Brodie, Jr. and Harry W. Greene, conveners. E. D. Brodie, Jr.; J. P. Caldwell; B. E. Dial; C. Edelstam; H. W. Greene.

• *Ecology and Conservation of the Tuatara.* Michael B. Thompson and Donald G. Newman, conveners; Marie-Charlotte Saint Girons, moderator. C. Carmichael; A. Cree; C. H. Daugherty; J. C. Gillingham; B. Green; L. J. Guillette and A. Cree; M. McIntyre; D. G. Newman; G. C. Packard, M. B. Thompson, and M. J. Packard; M. B. Thompson.

• *Herpetofaunas: A Biogeographic Review of the Continents.* Charles P. Blanc and Jay M. Savage, conveners. S. C. Anderson and A. E. Leviton; C. P. Blanc; D. G. Broadley; J. M. Savage; M. J. Tyler; P. E. Vanzolini.

• *Caecilian Biology and Evolution.* Michael Delsol and Marvalee H. Wake, conveners. J.-M. Exbrayat and M. Delsol; H. Greven; E. Gudynas; W. Himstedt; R. Laurent; J. Lescure and S. Renous; S. Renous, J.-P. Gasc, and J. Lescure; A. Smits; K. Schwenk; B. R. Seshachar; D. M. Walsh; M. Wilkinson; L. Zylberberg.

• *Snake Systematics and Phylogeny.* Herndon G. Dowling, Gregory A. Mengden, and Olivier Rieppel, conveners. H. G. Dowling; G. A. Mengden; J.-C. Rage; O. Rieppel; G. Underwood.

• *Laws, Research, and Conservation: A Conundrum.* Harold G. Cogger and Stephen R. Edwards, conveners.

• *Amateur Contributions to Herpetology.* Wolfgang Böhme, convener. H.-G. Horn; R. Guyétant; W. Sachsse; H. Zimmermann.

• *Medical and Herpetological Aspects of Venoms and Skin Toxins.* José M. Cei and Sherman A. Minton, conveners. G. De Caro; D. L. Hardy; E. Kochva; D. Mebs; H. Rosenberg; D. A. Warrell; J. White.

workshops

• *Skeletochronology and Aging Methods.* Jacques Castanet and Ella Smirina, conveners. R. Leclair, moderator. M. H. Caetano; J. Castanet and E. Smirina; M. Esteban, P. Herrero, and B. Arano; M. W. J. Ferguson and T. Joanen; R. Leclair; A. Montori; M. Sander; G. R. Zug.

• *Field Methods and Biotelemetry.* Jan van Gelder and R. Stuart Mackay, conveners. J.-P. Gasc; J. J. van Gelder; K. Grossenbacher; R. S. Mackay; J. P. Martínez-Rica; G. Naulleau, J. J. Ducamp, and A. Mariani; T. Pilorge and J. Clobert; R. Podloucky; M. Stanner.

• *Molecular Techniques.* David M. Hillis and Craig Moritz, conveners. L. D. Densmore, F. L. Rose, S. J. Kain, and R. T. Purkiss; D. M. Hillis; L. R. Maxson; C. Moritz; R. Murphy; J. Sites and R. Murphy.

• *Amphibian Larvae.* Barry D. Valentine and Richard Wassersug, conveners and presenters.

• *Quantitative and Phylogenetic Analysis.* Roger S. Thorpe and Garth Underwood, conveners. U. Joger; G. Mengden; M. Miyamoto; R. S. Thorpe; G. Underwood; J. W. Wright.

• *Photographic Techniques.* David Curl and David M. Dennis, conveners and presenters.

Posters

Many delegates participated in the congress by bringing posters describing their research. 370 posters were erected. Special times were set aside when authors were present at their posters to conduct discussions. Richard Tinsley served as Posters Manager.

• *Conservation and Management of Species.* K. H. Berry; L. A. Brandt; D. Corke; S. K. Dutta and P. Mohanty-Hejmadi; S. J. Incháustegui and Y. Arias; F. C. Killebrew; G. Kuchling; G. Kuchling and A. A. Burbidge; A. Muth; R. J. Rao; S. Shammackov; M. P. Simbotwe; M. Vyas, T. P. Vyas, and A. K. Pandey; T. Waller, P. A. Micucci, and E. Richard.

• *Effects of Environmental Pollution on Herpetofauna.* S. K. Bhatti and U. S. Bhatti; U. S. Bhatti and S. K. Bhatti; R. B. Bury and P. S. Corn; D. Dolmen and I. Blakar; M. Puky and N. Oertel; D. H. Taylor, S. Strickler-Shaw and C. W. Steele; R. Tzannetatou-Polymeni and A. A. Haritos.

Seal engraved by Hajime Fukada, Past President of Herpetological Society of Japan, to commemorate the First Congress. The Chinese characters read (right to left) "snake" and "propensity"—or "snake mania"—in allusion to herpetologists' devotion to their discipline and to the fact that the congress was held, appropriately enough, in the Chinese Year of the Snake. The seal is written in the Japanese *Ten* style of 1000-500 B.C.

• *Captive Management.* R. A. Acuña-Mesen; U. S. Bhatti and S. K. Bhatti; T. Boylan; L. G. Brown; J. F. Iaderosa; K.-H. Jungfer, W. Holmstrom, and J. L. Behler; S. V. Kudrjavtsev; V. K. Uteshev, O. I. Shubravy, I. A. Serbinova, and B. F. Goncharov; C. Warwick; H. Zimmerman.

• *Health and Disease.* B. Bannert; J. E. Cooper, R. Ewbank, C. Platt, and C. Warwick; M. E. Cooper; N. J. Millichamp, J. Dziezyc, and J. P. Flanagan; G. R. Pisani and B. R. Stephenson; I. Rácz and A. Kósa; V. Roca and M. J. Hornero; C. C. C. Samora, H. E. Coelho, R. E. C. Maitin, and R. C. Paulino; R. C. Sinha and R. P. Singh; J. C. Troiano.

• *Sexual Selection and Communication.* P. R. Y. Backwell and N. I. Passmore; U. S. Bhatti, S. K. Bhatti, and R. S. Sidhu; P. J. Bishop and N. I. Passmore; G. R. Bourne; M. Cherry and T. R. Halliday; F. M. Clarke and C. A. Hosie; L. Edsman; R. Günther and J. Plotner; T. R. Halliday and C. Giacoma; W. Hödl; C. A. Hosie; A. J. in den Bosch; R. W. Krohmer and D. Crews; R. M. M. de Orense; K. Ovaska; R. Pawley and V. H. Hutchison; C. J. Raxworthy; J. J. Schwartz; D. M. Sever; K. Summers; M. Tejedo; A. Zuiderwijk.

• *Environmental Sex Determination.* M. T. Dimond; M. A. Ewert and C. E. Nelson; J. L. Harry, K. L. Williams, and D. A. Briscoe; B. Jones, III and J. A. Musick; H. Merchant-Larios and F. I. Villalpando; S. Tokunaga; R. C. Vogt.

• *Orientation, Navigation, Nervous System and Senses.* A. Elepfandt, B. Schanz, B. Traub, M. Hainich, E. Günther, and A. Fleig; J. A. Keinath and J. A. Musick; Y.-P. Mou.

• *Egg Games: Optimal Size and Clutch Size.* C. K. Beachy; M. V. Subba Rao and M. Ratnakumari; Y. L. Werner and E. Frankenberg.

• *Long-Term Studies.* C. M. Bull; J. Burger and R. T. Zappalorti; A. Chandola-Saklani and V. D. Joshi; C. P. Cummins; J. Elmberg; K. Fog; F. J. Mazzotti, L. A. Brandt, and J. R. Wilcox; C. J. Reading.

• *Snake Behavior and Ecology.* A. L. Aghasian; A. Bea and J. P. Martínez Rica; A. Bouskila; P. R. Brown; K. Claus and R. F. Verheyen; J. A. Butler; H. S. Fitch and G. R. Pisani; A. Forsman; M. J. Gaywood and I. F. Spellerberg; M. Hasegawa; W. H. Martin; J.-C. Monney; A. Mori; A. Moser; K. J. Nelson and P. T. Gregory; G. Naulleau, J. J. Ducamp, and A. Mariani; G. R. Pisani and B. R. Stephenson; B. A. Savitzky; A. Solórzano López; B. R. Stephenson and G. R. Pisani; M.-C. Tu, C. M. S. Tsoi, S. H. Fong, and S. C. Lee; P. Vozenilek; K.-N. Xie; M. Zuffi.

• *Ecology and Adaptations in Extreme Environments.* M. R. Warburg.

• *Community Ecology.* A. Channing; I. de la Riva de la Viña; C. K. Dodd, Jr.; G. Moreira and A. P. Lima; I. Pavignano and C. Giacoma; D. Sanders, D. Bauwens, and R. F. Verheyen; P. Walker.

• *Herpetofaunas: Explorations and*

Studies. D. E. Barnard, J. A. Keinath, and J. A. Musick; L. Bodson; D. G. Broadley; M. A. Carretero; M. A. Carretero, X. Fontanet, G. A. Llorente, A. Montori, X. Pascual, X. Santos, E. Filella, S. Gimenez, L. Jover, C. Llorente, and N. Horta; N. Carrillo de Espinoza; J. Castanet and R. Guyetant; J. Dorda Dorda; A. Dubois and A. Ohler; J. R. Formas; J.-P. Gasc; I. V. Ghira and B. Stugren; M. L. Golubev; R. M. Gomez Prieto; H. Grillitsch and F. Tiedemann; U. Gruber; W. D. Haacke, R. Loutit, and S. G. Braine; T. I. Kotenko; Z.-T. Kou; R. C. Longmore; M. T. O'Shea; C. Pérez-Santos and A. G. Moreno; T. S. Sattarov; M. V. Subba Rao and B. Nageswara Rao; N. N. Szczerbak; J. Terhivuo; H.-P. Ting and J. Zheng; B. S. Tuniyev; J. Zheng.

• *The Ecology of Tuatara.* J. F. Cockrem, B. T. Firth, A. Cree, and G. R. Eynon; M. E. McIntyre.

• *Skeletochronology.* S. C. Buchholz; M. H. Caetano; P. Campolongo, H. Francillon-Vieillot, C. Giacoma, F. Rossi, and S. Tripepi; J. Castanet, M. Baez, and A. de Ricqlès; M. Esteban, P. Herrero, and B. Arano; V. G. Ishchenko; A. Juarranz, D. Patón, and A. Morales; G. R. Zug.

• *Field Methods and Biotelemetry.* E. Ferrandis, E. Seva, and P. Gracia; P. E. Ouboter; S. A. Sharygin; G. Sorci.

• *Origin of the Amphibia and Reptilia: Paleontological Evidence.* M. F. Ivakhnenko; R. R. Reisz and M. Laurin; R. Werneburg.

• *Paleoherpetology: Impact on Neoherpetology.* S. C. Anderson and A. E. Leviton; V. M. Ckhikvadze; R. Hernández-R., F. Soberón-M., and M. A. Cabral; G. A. Zerova.

• *Island Herpetofaunas.* M. Gaulke; A. Malhotra and R. S. Thorpe; M. Mylonas and E. D. Valakos; H. Ota; V. Pérez-Mellado and M. P. Galindo Villardón; R. M. Polymeni; G. H. Rodda and T. H. Fritts.

• *Caecilian Biology and Evolution.* J. M. Exbrayat and M. Delsol; W. Himstedt.

• *Molecular Systematics.* B. Arano, M. Esteban, and P. Herrero; C. Corti, M. Capula, and G. Nascetti; L. D. Densmore, F. L. Rose, S. J. Kain, and R. T. Purkiss; M. Garcia-Paris and B. Arano; T. Hayashi and M. Matsui; H.-W. Herrmann, U. Joger, and G. Nilson; F. R. Méndez-de la Cruz and G. Casas-Andreu; A. H. Price and D. M. Hillis; P. S. White and L. D. Densmore; C. W. Zeyl.

• *Cytogenetics.* R. G. Belcheva and Th. S. Sofianidou; B. D. Bell; T. Capriglione, A. Cardone, G. Odierna, and E. Olmo; M. Capula, F. Andreone, G. Nascetti, and L. Bullini; M. Capula, G. Nascetti, and L. Bullini; A. Cardone, T. Capriglione, G. Odierna, and E. Olmo; C. Chang and A. S. Rand; B. Fritz, W. Ulrich, and J. P. Fritz; E. H. Gadsden; P. Herrero, B. Arano, and M. Esteban; L. A. Kupriyanova; Z.-P. Lin, Z.-X. Wang, and K.-Q. Pan; S. G. Stewart and D. J. Morafka; M. Toriba; G. Wei and X. Ning; G. Wei, X. Ning, and D.-J. Li.

• *Parthenogenesis and Hybridogenesis.* R. L. Bezy; L. J. Borkin, R. Günther, Yu. M. Rozanov, and A. E. Vinogradov; W. M. Brown, L. D. Densmore, C. Moritz, and D. Peccinini-Seale; I. A. Caune and L. J. Borkin; F. D. Danielyan; I. S. Darevsky and T. M. Sokolova; L. D. Densmore, C. C. Moritz, J. W. Wright, and W. M. Brown; J.-D. Graf and M. Pols Pelaz; R. Günther; R. Günther and J. Plotner; H. Hotz and P. Beerli; N. Kamezaki; M. W. Klemens; F. Kraus and M. M. Miyamoto; L. A. Kupriyanova; B. E. Leuck; L. A. Lowcock; C. Moritz, C. Spolsky, H. Hotz, and I. Darevsky; M. E. Oliveira, M. Paillette, H. Rosa, and E. G. Crespo; D. Peccinini-Seale, C. Moritz, J. Sites, and D. Vyas; M. Polis-Pelaz and J.-D. Graf; H. G. Tunner and S. Heppich; J. W. Wright; J. W. Wright, D. Peccinini-Seale, C. Moritz, and J. Sites.

Official congress badge—a metal base painted in gold and blue—donated by Ilya S. Darevsky and his Soviet colleagues and presented to congress delegates.

• *Systematics and Phylogeny.* L. Bauer; D. P. S. Bhati; R. P. Brown and R. S. Thorpe; H. Griffith; H. J. Herrmann; A. V. Koroljov, S. M. Moody and M. M. White; A. Ohler; A. G. J. Rhodin; H. Sisniegas; W. Wüster and R. S. Thorpe; A. Young-Downey and J. Moreno.

• *Snake Systematics and Phylogeny.* R. A. Knight, L. D. Densmore, and E. D. Rael; I. Rehák; L. M. Reyes, E. Habacon, R. Tansiel, and D. Morafka; J. B. Slowinski; A. A. Tokar; G. Underwood.

• *Phylogenetic Analysis.* U. Caramaschi; D. R. Frost and R. Etheridge; A. Gubányi and Z. Korsós; T. Hikida; R. S. Thorpe.

• *Energetics.* Y.-K. Bai; R. A. Coulson, T. D. Coulson, and J. D. Herbert; T. Dellinger; B. E. Dial; N. M. Grimmond; F. V. Paladino, M. P. O'Connor, and J. R. Spotila; R. Vernet.

• *Ecological Physiology.* M. Alcobendas; M. E. Allen and O. T. Oftedal; D. J. Baer, O. T. Oftedal, and C. L. Kirk; N. G. Basso and J. D. Williams; C. Carey and J. R. Hazel; C. B. Daniels, P. J. Hayball, H. A. Barr, P. B. Frappell, and T. E. Nicholas; H. Ditrich and H. Splechtna; A. S. Gardner; W. Geise; L. E. Hunt; A. I. Kehr; G. Perry and R. Dmi'el; C. F. D. Rocha; M. G. Rovedatti, P. M. Castañé, and A. Salibián; R. Ruibal and E. J. Carroll, Jr.; A. Salibián; G. Sarig and G. Avital; R. C. Sinha and S. K. Singh; E. D. Valakos; R. Van Damme, D. Bauwens, M. A. Castilla, and R. F. Verheyen; B. Viertel; P.-C. Wang, X. Ji, and W. Ma; R.-M. Wu; R. L. Wyman and M. P. Frisbie.

• *Functional Morphology.* P. C. Arena and K. C. Richardson; L. J. Barbadillo; V. L. Bels; J. Cleuren, G. De Gueldre, and F. De Vree; J. Cleuren, V. Timmerman, and G. De Gueldre; J.-P. Gasc and S. Renous; V. Goosse and V. L. Bels; J. Klembara; T. M. Környei; D. B. Miles; J. L. Putnam; S. Renous, V. Bels, and J. P. Gasc; N. Salomatina; J. P. N. Singh; L. A. Somma; J. Weisgram and H. Splechtna.

• *Reproductive Physiology.* D. G. Brust; R. L. Burke; J. M. Cei, N. Ibanez, M. Zerani, and A. Polzonetti-Magni; H. Y. Cheng; C. Gascon; T. U. Grafe; S. Jacobs and J. H. Van Wyk; E. Limatola, F. Neumann; J. C. Ortiz and H. Ibarra-Vidal; S. K. Raut; R. Schabetsberger; I. Schlupp and R. Podloucky; B. Seidel; M.-T. Song.

• *Lizard Ecology and Behavior.* D. B. Carter; A. M. Castilla and D. Bauwens; S. C. Castillo; A. Chandola-Saklani and V. D. Joshi; A. Foà, A. Nieri, and G. Tosini; S. J. Incháustegui and Y. Arias; L. S. Melkumian; C. J. Pollo and V. Pérez-Mellado; S. R. Singh, U. S. Bhatti, and S. K. Bhatti; S. R. Singh and B. S. Kaur.

• *Chelonian Ecology and Behavior.* P. Crucitti, A. Campese, and M. Malori; V. E. Frolov; D. Margaritoulis; I. N. S. Nuitja; J. M. Sutherland and R. Woods; D. S. Wilson.

Other Events and Presentations

In addition to the main scientific program described above, there were numerous other events. The IUCN Species Survival Commission, chaired by George B. Rabb, met at the congress, as did several of its specialist groups concerning reptiles. A meeting of the African Amphibian Group was arranged by Jay M. Savage. A Herpetological Quiz, covering world herpetology and including laboratory displays, was organized by Martha Crump and assisted by Garth Underwood.

An auction of donated herpetological materials (books, prints, original artwork, paraphernalia), organized by Michael Lambert, was held one evening before a large, "spirited" audience. About $4000 was raised by Joseph T. Collins, the auctioneer, and his assistants, Ruth Zantzinger and Ellin Beltz; the proceeds will support worthy amphibian and reptilian conservation projects, worldwide.

A two-hour-long Herpetological Audiovisual Extravaganza was held, consisting of three sound-and-slide programs which required six computer-controlled slide projectors and a 4-by-10-m screen. "Herpetology Past and Present," an hour-long presentation by David M. Dennis and Kraig Adler, featured photos of herpetologists, their institutions, and illustrations of amphibians and reptiles from earliest times to the present, accompanied by classical and modern music, and was international in coverage.

Two shorter AV programs by Dennis and J. Eric Juterbock, "Amphibians of the Appalachians" and "Herpetology of the American West," comprised photos of animals and their habitats, accompanied respectively by the music of Aaron Copeland and Igor Stravinsky, and included breathtaking full-screen panoramas of some of the most famous herpetological localities and North American scenery. These three programs, officially sponsored by SSAR, were shown a total of seven times, by popular demand, and were described by members of the French contingent as "formidable!"

There were a large number of commercial exhibits, arranged by Thomas E. S. Langton, including book and print dealers, publishers, conservation displays, and herpetological society membership booths. In addition, numerous congress memorabilia were produced for sale, such as men's ties, crystal paperweights, medallions, and T-shirts decorated with the congress chameleon logo.

The congress Press Office, staffed by two persons, provided regular reports to television and print media of the most important research and conservation news from the congress.

Publications

Each delegate received several congress publications, including a 110-page Program. The 334-page Abstracts volume, containing half-page summaries of each oral and poster presentation, was organized by Tim Halliday. (Unfortunately, no extra copies are available for sale.) Delegates also received a specially-bound congress edition of SSAR's latest book, *Contributions to the History of Herpetology*, by Kraig Adler, John S. Applegarth, and Ronald Altig, as a gift from the Society.

WCH Executive and Business Meetings

The Executive Committee of the World Congress met four times during the congress and the Business Meeting attracted about 200 delegates. Business included ratification of the WCH Constitution, endorsement of WCH's continuing editorial responsibility for the series *Amphibian and Reptilian Species of the World*, establishment of a Committee on Nomenclature to respond to requests from the International Commission on Zoological Nomenclature, election of new members to the Executive and International Herpetological Committees (EC and IHC) of WCH, passage of resolutions, and discussion of a venue for the Second Congress.

After discussion at the Business Meeting, the new Constitution was approved unanimously. Among other provisions, this affords a mechanism for election of new EC and IHC members

The Executive Committee of the World Congress of Herpetology, in session at Canterbury. Left to right, seated: Michael R. K. Lambert (UK), Marinus S. Hoogmoed (*Treasurer*; Netherlands), P. E. Vanzolini (Brazil); standing: Gustavo Casas-Andreu (Mexico), Robert L. Carroll (Canada), Ermi Zhao (China), Ilya S. Darevsky (USSR), Rainer Günther (German D.R.), Donald G. Broadley (Zimbabwe), Harold G. Cogger (Australia), Kraig Adler (*Secretary-General*; USA), Ian R. Swingland (*Ex officio*; UK), and Hubert Saint Girons (France). Also present but not pictured: José M. Cei (Argentina/Portugal) and David B. Wake (USA).

(who will serve for two inter-congress terms, with half of both committees being replaced at each congress to provide for continuity and renewal) and future congresses at intervals of 3-5 years.

The Secretary-General and some other members of the EC declined renomination and ten persons were thus newly elected to the EC, which now consists of (new members*): Roger A. Avery*, Wolfgang Böhme*, Donald G. Broadley, Robert L. Carroll, Gustavo Casas-Andreu, Harold G. Cogger, J. C. Daniel, Ilya S. Darevsky, William E. Duellman*, Tim R. Halliday*, Marinus S. Hoogmoed, Konrad Klemmer*, Michael R. K. Lambert, Jean Lescure*, Jay M. Savage*, P. E. Vanzolini, Marvalee H. Wake*, Yehudah Werner*, Romulus Whitaker*, and Ermi Zhao.

The 50-person IHC is now comprised of (new*): Rafael A. Acuña Mesen*, Pere Alberch*, Jean-Louis Amiet, Natalia B. Ananjeva*, Claes Andrén*, E. Nicholas Arnold, Ana Maria Báez*, İbrahim Baran, Willy Beçak, Ben D. Bell, Leo Borkin*, S. D. Bradshaw*, William R. Branch, E. R. Brygoo, Jacques Castanet*, Charles H. Daugherty*, Alain Dubois*, J. Ramón Formas, Darrell Frost*, Carl Gans, David M. Green*, Harold Heatwole, René E. Honegger, Robert F. Inger, Ulrich Joger*, Raymond F. Laurent*, Murray J. Littlejohn*, Shou-hsian Mao, Linda R. Maxson*, Roy W. McDiarmid*, Göran Nilson*, Georges Pasteur, Eric Pianka*, Jens B. Rasmussen*, Armand de Ricqlès, Olivier Rieppel*, Zbyněk Roček*, Borja Sanchíz*, Yoshio Sawai, Richard Shine*, Malumo P. Simbotwe*, Zdeněk V. Špinar, Ian R. Swingland*, Leonid P. Tatarinov, Franz Tiedemann, Richard C. Tinsley*, Linda Trueb*, Michael J. Tyler, Richard Wassersug*, and George R. Zug.

Three resolutions were introduced and discussed. The first, concerning the use of turtle-excluder devices (TEDs) on nets of shrimp boats in the Gulf of Mexico, to reduce the killing of sea turtles, was passed. This resolution subsequently was sent to the Hon. George H. W. Bush, President of the USA. The second resolution concerned the conservation of European herpetofauna and asks for governmental attention to various aspects of conservation. This statement was also passed and copies were sent to the European Parliament and other European governmental bodies. A third resolution, intended to recognize the important contributions of amateur herpetologists to captive husbandry, was, after lengthy discussion, defeated. The delegates, although sympathetic with the intention, felt that such a statement could be misused by some dealers and unscrupulous amateurs.

Formal invitations to hold the next congress in Adelaide (Australia), San José (Costa Rica), or Singapore were discussed. Further invitations are being solicited, but the EC expects to make a final decision early in 1990.

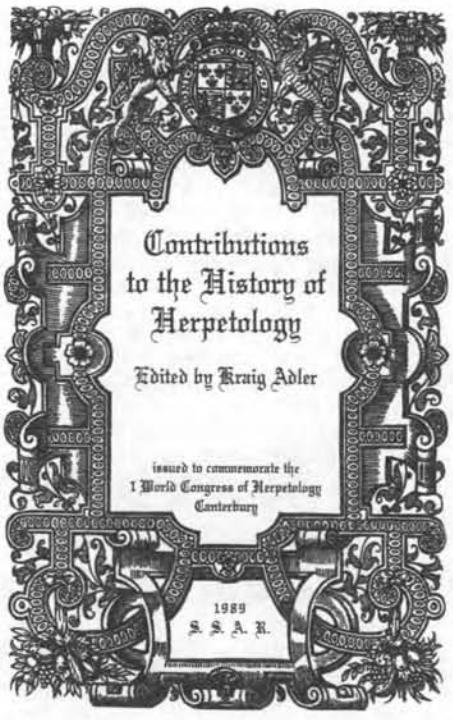
Social Activities

Social activities were held every evening during the conference, to give relief from the intensive daytime scientific sessions and to provide other opportunities for interaction and discussion. The Lord Mayor of Canterbury and the City Council hosted an elaborate reception at the old Westgate Gardens in the city, at which we were entertained by the Canterbury Pipe Band, a highland bagpipe band dressed in full Scottish regalia, and two local troupes, including Morris dancers, demonstrating traditional English country dances. Other evenings featured a discothèque, receptions (the wine was excellent), and film programs.

The WCH banquet was a formal affair, with music by Dixieland and jazz bands, at which the congress hosted the Lord Mayor, the Sheriff of Canterbury, the university's Vice-Chancellor, and other Canterbury and university dignitaries. As was fitting for an occasion of this nature in the United Kingdom, the Secretary-General, on behalf of the delegates, led the formal tribute—called the "loyal toast"—to Her Majesty Queen Elizabeth II.

One day midway through the meeting was free of all scientific sessions, allowing delegates and families to relax or participate in guided tours to London, Paris, and other places, although tours were also conducted on other days. Some delegates visited Down House, home of Charles Darwin, now a museum just a short distance west of Canterbury.

On the final evening of the congress there was an enormous outdoor barbeque on a hill overlooking the city, where delegates and their families ate pork ribs and chicken *ad libitum*, washed down with another special congress brew, "Snake Bitters." The 70-member Regimental Band of the Royal Green Jackets, a regular British Army unit stationed near Canterbury, displayed the famed pagentry of the British military by playing martial music while marching in several drill formations to entertain the audience.



On other evenings there were numerous informal gatherings of groups of herpetologists, some of which had never met before as a group (for example, herpetologists from the Soviet Union and China, who met for the first time, and another group from throughout Latin America) and, in other cases, national groups (Canada, New Zealand, etc.) and groups with taxonomic or functional areas in common.

Closing Ceremonies

On the last day, following the final plenary lectures at the Marlowe Theater downtown, the First Congress was brought to a formal close by Kraig Adler. He noted the intensity of the week's activities, the evident enthusiasm for the next congress, and the presence in the audience of numerous senior colleagues from around the world as well as many young herpetologists, the youngest of whom was a 15-year-old amateur from Ohio in the USA.

As examples of the eagerness to attend this congress, Adler mentioned one delegate who sold his automobile to obtain the necessary funds, and another who borrowed from friends and relatives overseas and who expects that it will take 10 years to repay the loans. He then called on Michael Lambert, authorized by the WCH Executive Committee to read out the following resolution of appreciation:

• *"Recognizing the contribution made in convening the two World Congress committees (the Executive Committee and International Herpetological Committee) and by integrating the interests of the entire herpetological community with those in the United Kingdom for the First World Congress of Herpetology, and the dedication and personal commitment of the Secretary-General on behalf of herpetology and herpetologists worldwide, the profound thanks of the Congress participants are due to Kraig Adler.*

Contributions to the History of Herpetology, a book published by SSAR to commemorate the First Congress, was issued in a special edition at Canterbury. The book includes biographies of 152 leading herpetologists (with their portraits and signatures), an index to 2500 authors in taxonomic herpetology, and academic lineages of 1300 herpetologists, worldwide. The regular cloth-bound edition is available for $20 postpaid from the Publications Secretary, Robert D. Aldridge (address inside front cover of this issue); see full description in the March 1989 issue of *Herp Review* (centerfold).

• *"Acknowledging the assistance in the development and functions of the World Congress of Herpetology, the Executive Committee, on behalf of the world's herpetologists, wish to express their gratitude to:*

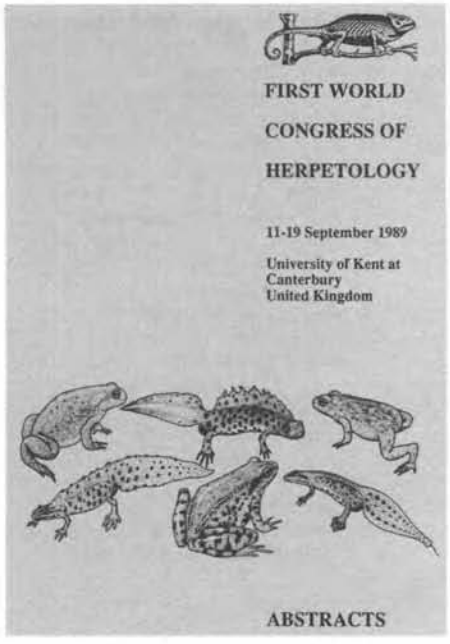
"1. William Duellman, David Wake, and John Wright, members of an original ad hoc *committee which initiated the founding of the World Congress and put the proposal to American and foreign representatives attending the Silver Anniversary Meeting of the Society for the Study of Amphibians and Reptiles and of the Herpetologists' League in Raleigh, North Carolina, August 1982.*

"2. Members of the World Congress Constitution Committee: Harold Cogger (Chairman), Natalia Ananjeva, Richard Goris, René Honegger, Jay Savage, and P. E. Vanzolini.

"3. Members of the First World Congress Subsidy Panel: Marinus Hoogmoed (Chairman), Roger Avery, Wolfgang Böhme, John Burton, Carl Gans, Harold Cogger, Michael Lambert, Raymond Laurent, and Jay Savage.

• *"Recognizing the value of the work put into developing and maintaining the smooth running of the First Congress, the Executive Committee, on behalf of the participants, have very great pleasure in expressing their deepest gratitude to all those people in the United Kingdom involved with administering the First World Congress of Herpetology, especially: Ian Swingland (Conference Director), together with Fiona Lawson, alias Mrs. Ian Swingland (Records Manager), without whose phenomenal and stalwart efforts the First World Congress of Herpetology might not have happened at all, as well as the following persons:*

"David Bateman (Database Manager), Richard Griffiths (Stewards Manager), the Earl of Cranbrook (Convener of Honorary Officers), Roger Avery (Chairman, UK National Executive), Roger Thorpe (Symposia Manager), Richard Tinsley (Posters Manager), Timothy Halliday (Abstracts Manager), Henry Arnold (Films Manager), Trevor Beebee (Workshops and Roundtables Manager), Michael Lambert (Auction Manager), Garth Underwood (Quiz Manager), and the Senior Stewards: Quentin Bloxam, Arnold Cooke, John Cooper, Keith Corbett, Peter Davies, Brian Groombridge, Thomas Langton, Robert Oldham, Peter Olney and David Stubbs.



"At the University of Kent: David Ingram (Vice-Chancellor), Peter Jordan (Conference Officer), Elizabeth Cable (Deputy Conference Officer), Neville Holloway (Catering Manager), and John Pell (Audio-Visual Aids Manager). In the City of Canterbury: Arthur G. Porter (Lord Mayor of Canterbury) and William Preston (Secretary, Canterbury City Council).

"Richard Griffith's team of Congress stewards, especially Margaret Bray, David Curl, David Galbraith, Adrian Hailey, Hinrich Kaiser, Michael Klemens, Mark O'Shea and Ralph Wycherley, and including Begona Arano, Paul Beckwith, Joseph Bernardo, David Bird, Lee Brady, Anne-Marie Brennan, Richard Brown, Angela Buckley, Rob Colby, Will Crampton, Jenny Daltry, Paul Edgar, James Foster, Luis García-Hidalgo, Rosa Gómez-Prieto, Andras Gubányi, Olive Lindstrand, Anita Malhotra, Tricha Murphy, Miklós Puky, Sheik Rashid, S. K. Raut, Julie Roberts, Zbyněk Roček, Antonio Salas Jaramillo, Robert Schabetsberger, Birgit Stangl, Mary Swann, Verina Waight, Gang Wei, Rona Williams, Jaclyn Wolfheim, Pieter de Wijer, Galina Zerova, and Robert Macey.

• *"Some accompanying persons, to assist needy overseas delegates, became booksellers, namely Dolores Adler and Patricia Zug.*

Scheduled intermissions allowed speakers and their audience—here, from the symposium on "Health and Disease"—to talk informally, in lounges near the meeting rooms.

The 334-page Abstracts volume contained half-page summaries of all oral and poster presentations. The drawings, by Tim Halliday, depict the six British amphibians. Britain's reptiles appeared on the cover of the Program.

• *"Numerous other individuals and organizations have contributed towards the organization of the First World Congress of Herpetology in a variety of ways, and the Executive Committee take this opportunity to thank them also. These include: Martha Crump (Herpetology Quiz originator), Joseph Collins (auctioneer), assisted by Ruth Zantzinger and Ellin Beltz, David M. Dennis (originator and organizer of the Audio-Visual Extravaganza) and his collaborators, J. Eric Juterbock and Kraig Adler; the Society for the Study of Amphibians and Reptiles for donating the Congress Poster (painted by David Dennis) and the book* Contributions to the History of Herpetology *(edited by Kraig Adler); and Ilya Darevsky and his colleagues in Leningrad for the official congress badge.*

• *"And for being everywhere at the same time (besides Ian Swingland): Kraig Adler."*

After the names of persons newly elected to the Executive and International Herpetological Committees of the World Congress were reported, Kraig Adler announced the results of the Executive Committee's election of senior officers earlier in the day. Robert L. Carroll (Canada) was elected Treasurer and Marinus S. Hoogmoed (Netherlands) as the new Secretary-General. Marinus Hoogmoed then assumed his new office and, after some brief remarks, declared the First Congress closed.

J. ERIC JUTERBOCK
SSAR Secretary •

SSAR ELECTION RESULTS

The results of the 1989 SSAR election are as follows:

President-elect ..... Linda E.R. Maxson
Secretary ..... J. Eric Juterbock
Treasurer ..... Douglas H. Taylor
Board - Regular ..... Henry R. Mushinsky
Board - Zoological Parks .....Gustavo Casas-Andreu

A total of 658 members voted in this election.

The Society extends its gratitude to the Nominating Committee (James B. Murphy, Chair) and to the SSAR Elector (Ruth M. Zantzinger) for their hard work, and to the outgoing president and board members for their service during their terms.

NEWSNOTES

LONGEVITY SURVEY

The deadline for submitting data to the new edition of *Longevity Survey of Reptiles and Amphibians in North American Collections* is 31 May 1990. Please submit data to Kevin Bowler or Andy Snider, Audubon Zoo, 6500 Magazine Street, New Orleans, LA 70178, USA ●

CROCODILIAN SYMPOSIUM PROCEEDINGS

A separately bound reprint of the symposium *Biology of the Crocodilia* that appeared in Volume 29, number 3 of the American Zoologist, September 1989, is available from Valentine Lance, Center for Reproduction of Endangered Species, San Diego Zoo, P.O. Box 551, San Diego, CA. 92112, USA. The reprint is soft-bound, 232 pages in length and consists of 15 major papers, a brief biography of Professor Roland Coulson, to whom the symposium was dedicated, and an afterword by Professor Carl Gans. Copies may be purchased for $10 U.S., including postage. Make checks payable to the Zoological Society of San Diego, include a notation on the check "account #3-2022-875/972-Lance," and mail to V. Lance. Prepaid orders only please in U.S. dollars. ●

DALLAS ZOO SEEKS ZOOLOGIST

The City of Dallas Park and Recreation Department is seeking qualified applicants for the position of Zoologist 12 in the Reptile Department of the Dallas Zoo. Responsibilities include research program development and coordination as well as assisting department curators.

Qualified applicants must have a bachelor's degree in zoology or a related field and two years of research experience. Knowledge of the behavior, ecology and physiology of reptiles is highly desirable, as is a degree beyond the bacheolor's level.

Salary range is $22,344-27,132, depending upon education and experience. Applicants should state they are applying for the Zoologist 12/Reptile Department position in the Park and Recreation Department, and submit applications/resumes by 15 May 1990 to: Staffing Manager, Personnel Department, 1500 Marilla, City Hall Room 6AM, Dallas, TX 75201, USA ●

SOCIETIES

ADDRESS CHANGES

The following address changes have been submitted since the list of herpetological societies was printed in the September 1989 issue of *Herpetological Review:*

American Society of Ichthyologists and Herpetologists
Florida State Museum
University of Florida
Gainesville, FL 32611, USA

Herpetologists' League
Texas Natural Heritage Program
Texas Parks & Wildlife Department
4200 Smith School Road
Austin, TX 78744, USA

Nordisk Herpetologisk Forening
Mr. Henrik Bringsoe, Chairman
Esthersvej 7
DK-4600 Koge
Denmark

Oklahoma Herpetological Society
c/o Bob Ball, Newsletter Editor
Route 1, Box 59
Goodwell, OK 73939, USA

Terrariengemeinschaft Berlin E. V.
Mr. Peter Grossman
Lepsiusstrasse 53
D-1000 Berlin 41
Federal Republic of Germany

Society officers are encouraged to forward to the SSAR Regional Society Liaison (see inside front cover of *HR*) any address changes for their society. Newly formed societies are invited to announce their existence in this column. ●

FEATURES

SEXUAL SELETION AND COMMUNICATION IN AMPHIBIANS AND REPTILES

The First World Congress of Herpetology was held at the University of Canterbury in England from 11-19 September 1989. In attendance were over 1,000 amphibian and reptile biologists from over 60 countries. Included in the Congress program were six workshops, 11 roundtables and 27 symposia. One of the latter, the subject of this article, was devoted to studies of sexual selection and communication in amphibians and reptiles (17 September). It was convened and moderated by Murray Littlejohn (University of Melbourne, Australia) and Stevan Arnold (University of Chicago, USA).

Darwin (1871) developed the theory of sexual selection in order to account for the evolution of behavioral and morphological characters (usually exhibited by males) that function solely in the acquisition of mates. The symposium largely was focused on one aspect of sexual selection, intersexual selection or mate choice. This can be defined operationally as any pattern of behavior that leads to members of one sex (usually females) being more likely to mate with certain members of the opposite sex than with others (Halliday 1983a). The second aspect of sexual selection, competition among members of one sex (usually males) for access to members of the opposite sex, also received some attention.

Intersexual selection implies that information is being sent by certain individuals and is

HOLBROOK PORTRAIT

John Edwards Holbrook (1794-1871), the Father of North American Herpetology, was a physician living in Charleston, South Carolina. His two classic books, "North American Herpetology" (first edition, 1836-1840; second edition, 1842) were the first comprehensive surveys of the North American herpetofauna. In 1856-1857, Daniel Huntington painted an oil portrait of Holbrook, which has now been reproduced in full color as a poster measuring 8 3/4 x 11 1/4 inches and printed on heavy, acid-free stock suitable for framing. Copies are available for $6.00 each or $4.00 in quantities of 10 or more, postpaid, from SSAR Publications Secretary, Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103, U.S.A. (Copies of SSAR's 1976 reprint of Holbrook's "North American Herpetology," 1032 pages, 147 plates with 20 in color, clothbound, are also available from Dr. Aldridge, at $60.00 postpaid.)

being received by others. In other words, there is communication between sender and receiver, with some aspect of the behavior of the former influencing the behavior of the latter (Slater 1983). The functions of communication during intersexual encounters include the following (Tinbergen 1953; Halliday 1983b): (1) orientation or attraction of partners, often over a considerable distance; (2) "persuasion," whereby one partner increases the sexual motivation of the other in order to elicit a positive sexual response; (3) synchronization of the activities between partners to ensure the highest probability of successful reproduction; (4) species identification, and (5) assessment of some aspect of the "quality" of an individual as a mating partner.

The symposium reported studies of intersexual communication in the context of all five functions listed above. First, physiological (especially endocrinological) mechanisms which ensure intersexual synchrony in the reproduction of reptiles were considered. The majority of papers discussed aspects of mate choice by females of conspecific males. Finally, the role of sexual selection at the level of groups of populations and species was considered, especially in the context of species identification and the speciation process itself.

In this article, I briefly review the papers which comprised the symposium on sexual selection and communication in amphibians and reptiles. The reader will notice that all but one of the 11 papers deals with amphibians, and that of these, all but two deal with anurans.

Reproduction is the single most important event in the life of any organism. To be successful, individuals must time reproduction such that young are produced during a season when they are most likely to survive. In addition, there must be a high degree of synchronization among partners for successful reproduction. David Crews (University of Texas at Austin, USA) discussed his work on two North American reptile species which achieve these two types of synchronization in rather different ways.

In the lizard *Anolis carolinensis,* seasonal changes in the environment trigger neuroendocrine events in males which stimulate both spermatogenesis and the production of male sex hormones by the testis. These hormones then feed back onto centers in the brain to activate both aggressive (directed to other males) and sexual (to females) behavior patterns. Crews has found that male behavior can profoundly influence the rate at which the ovaries of females become ready for reproduction. Male courtship display speeds ovarian growth, whereas aggression among males inhibits it.

Synchronization occurs differently in the snake *Thamnophis sirtalis.* Lengthy winter hibernation and the need to produce young by late summer have resulted in the uncoupling of the processes of spermatogenesis, steroid production and mating behavior in males. Males mate at a time when their testes are regressed; higher spring temperatures directly activate courtship. Female ovaries are also regressed at this time, and develop only after mating activates crucial neuroendocrine events.

The concept of persuasion in intersexual communication was developed by Lynn Houck (University of Chicago, USA), who presented the results of her studies of sexual behavior in the North American plethodontid salamander *Desmognathus ochrophaeus.* As in many salamander species, male *D. ochrophaeus* deliver courtship pheromones to females during the initial stages of courtship. These pheromones are produced by specialized glands maximally developed only in sexually active males, and are delivered to females only during courtship (thus they are not the same as sex attractants, which operate over longer distances and before the initiation of courtship).

Houck demonstrated experimentally that exposure of females to the male's courtship pheromone renders them fully sexually responsive in a time shorter than that shown by females exposed to males in the absence of pheromone. The courtship pheromone apparently functions to "persuade" the female to mate by increasing her sexual responsiveness above some critical threshold level. In other experiments, Houck has demonstrated that there is considerable variation among males in their success at inseminating females. At least some of this variation may be due to differences among males in the timing of pheromone delivery.

Behaviors which males use to attract and/or stimulate females may incur costs as well as the obvious benefit of increased mating success. Thus a behavior might attract predators as well as potential mates. In frogs, calls used to attract females also may be costly because they are energetically expensive to produce; in some species, calling is the most expensive activity an individual can perform. Kent Wells and Ted Taigen (University of Connecticut, USA) studied the energetics of calling in two treefrogs, with particular emphasis on how the cost of calling changes with increased levels of acoustic competition among males.

In the North American frog *Hyla versicolor,* males call for longer durations when exposed to the calls of other males, but show a decrease in calling rate. Because of this trade-off, vocal interactions among males appear to have little influence on the energetics of calling in this species. Males appear to be close to their maximum ability to call most of the time, the ceiling of which probably is set by the availability of glycogen in muscles. The situation is rather different in *H. microcephala* from Central America. When exposed to the calls of other males, a male of this species adds notes to his own call and increases his rate of calling; the cost of calling increases with increasing chorus size.

Increased rate of calling is only one means by which a male can attempt to maximize the efficiency of his own calls in attracting females. Another is for the male to time the production of his calls so as to avoid overlap with the calls of his neighbors. In this way he increases the conspicuousness of his own calls. Peter Narins (University of California at Los Angeles, USA) predicted that avoidance of overlap should occur in choruses of the Puerto Rican frog *Eleutherodactylus coqui,* because it is the properties of the call notes themselves (not internote intervals) that are important in male aggression and female attraction. Narins developed a model based on this prediction in which a given male actively avoids overlap with, at most, two neighbors. When Narins tested his model with data collected from natural frog choruses he found that, indeed, males avoid overlap with one or two neighbors.

Frog calls have been studied using a number of different approaches, including behavioral studies of phonotaxis, computer-modelling and neurophysiological investigations of the auditory system. Michael Ryan and his colleagues (University of Texas at Austin, USA) presented evidence that physiological properties of the female auditory system might direct the evolution of male calls. In the frogs *Physalaemus pustulosus* (Central America) and *Acris crepitans* (North America) the auditory system of females is able to process a range of acoustic parameters far wider than the range which is typical of the species. As a consequence, once a call type evolves, properties of the female auditory system can exert directional selection on certain call characteristics (e.g., dominant frequency), thus directing their evolution. The sensory apparatus of the female clearly is an important factor in shaping the evolution of male vocalizations.

Chorus behavior in a natural population of the South African frog *Hyperolius marmoratus* was described by Neville Passmore and his associates (University of the Witwatersrand, South Africa). Male frogs and their calling sites were individually marked, and the males' activities were monitored in detail over a four week period. Chorus sizes varied greatly, and the night-to-night turnover of males was high. Considerable variation among males in mating success was found, with some males mating repeatedly and some not at all. However, large males were no more likely to obtain matings than were smaller males. A better predictor of male mating success was the number of nights that a male spent calling to attract females; the more nights, the greater his chances of mating.

That large males were not at an advantage in natural choruses is surprising, for experiments on phonotactic responses of female *H. marmoratus* have shown that call characteristics typical of larger males are preferred by females. In such experiments it is usual for there to be little or no background noise upon which specific call stimuli are superimposed. What is the relationship of the results of phonotaxis experiments to patterns of male mating success seen under more complex, natural conditions?

To answer this question, Mandy Dyson (University of the Witwatersrand, South Africa) studied male mating success in a caged population of *Hyperolius marmoratus* in which she manipulated male density (and thus the amount of background noise each male was forced to call against). Large males, producing the most attractive calls, were more likely to mate than were smaller males at low densities. However, at higher densities, Dyson found that this large-male advantage disappeared, with patterns of male mating success becoming random with respect to body size. Dyson suggested that increased background noise at higher densities resulted in high levels of acoustic interference. As a consequence, female mating preferences could not be effectively expressed.

Male mating tactics and patterns of male mating success have been studied extensively in the bufonid anurans. Considerable

variation exists both within and among species in the tactics used by males to acquire mates, e.g., calling from fixed sites, the adoption of silent satellite tactics and intense scramble competition. Similarly, there is great variation in the degree to which males of certain phenotypes are more successful in mating.

Anthony Arak (University of Oxford, England) considered the causes of intraspecific variation in male behavior in toads. He argued that individual males adopt tactics likely to give them the highest probability of mating based on their own phenotype (e.g., body size) and prevailing conditions at the breeding site, Of the latter, male density and the ratio of males to reproductive females (the operational sex ratio) are the most important factors. Female bufonids are far from passive, however. In many species, females prefer as mates those males that produce the most conspicuous calls. However, as with *Hyperolius marmoratus,* the extent to which a female can effectively express her choice depends upon the intensity of competition among males.

That females benefit from choosing particular males as mates is obvious in those cases where males defend some resource necessary for successful reproduction by females. The situation is less clear in those species in which males provide only genes to their offspring. Bruce Woodward (University of New Mexico, USA) reported the results of experiments on the relationships between male body size and offspring performance in North American anurans (*Scaphiopus, Bufo, Hyla*).

Woodward found that mating success among males is non-random in many natural breeding assemblages. Female choice might be responsible for the mating advantage enjoyed by larger males. By carefully splitting clutches of eggs of individual females between large and small fathers, Woodward showed that offspring performance is greater when fathers are large than when small. For example, juvenile *S. multiplicatus* grow faster if their fathers are of large body size. For anurans that occupy temporary ponds, differences in the timing of metamorphosis and/or size of offspring at metamorphosis might make all the difference between successful or failed reproduction. Woodward argued that female choice for larger mates is advantageous if larger males sire superior offspring.

Encoded within the call of a male frog are a number of types of information, such as his species identity and body size. Both types of information may be used by females in making mating decisions. Carl Gerhardt (University of Missouri, USA) analyzed call preferences in two North American treefrogs, *Hyla versicolor* and *H. chrysoscelis.* In experiments on phonotactic responses in both species, females preferred synthetic calls with characteristics typical of their species. However, for calls with characteristics within the limits of their species, females preferred calls which are both energetically expensive to produce and which are produced by large males. Gerhardt suggested that females use the same male calls to select both mates of the correct species and mates of superior phenotype. Interestingly, field studies of natural breeding populations of these treefrogs revealed no tendency for large males to have a mating advantage, a result echoing that for *Hyperolius marmoratus.*

Gerhardt also explored the possibility that the presence of one species might select for greater differences in the call of another, decreasing the likelihood of mistaken interspecific mating (and reproductive failure). Call pulse rate in *Hyla chrysoscelis* was found to vary over a broad geographic scale, but this variation apparently was unrelated to the presence of *Hyla versicolor.*

The evolution of behavioral mechanisms which prevent interspecific gene flow also was considered in the last paper in the symposium. Paul Verrell (University of Chicago, USA) reported that geographically isolated populations of the salamander *Desmognathus ochrophaeus* may differ so greatly in aspects of their sexual behavior that they fail to mate with one another in the laboratory. The degree of sexual isolation among populations increased with increasing geographic distance, presumably because distant populations have been separated for the longest time and have the lowest rates of gene flow. Interestingly, sexual isolation was not significantly related to the degree of genetic differentiation among populations.

Verrell's data indicate that differences in sexual behavior which prevent gene flow among species occur in sympatry may evolve while populations are isolated from one another in allopatry, perhaps under the influence of sexual selection. Observation of heterosexual encounters among individuals from different populations revealed considerable variability in just when in the courtship sequence such encounters break down to result in isolation. Both olfactory and behavioral differences among populations are implicated in the emergence of sexual isolation.

Announcement

SNAKES OF THE AGKISTRODON COMPLEX

by the late Howard K. Gloyd and Roger Conant

•

Due to unforeseen delays, publication of this book will be delayed until late summer 1990. The color plates are printed and the text is now completely typeset and in page proof, but additional work is required to prepare the text for printing.

•

SSAR greatly regrets this inconvenience to subscribers and asks for their continuing patience.—The Editor

PHORID FLY LARVAE AS PREDATORS OF TURTLE EGGS

The egg is one of the most vulnerable stages in the life cycle of turtles. Mortality factors include: erosion of the surrounding substrate, mechanical damage to the shell, changes in the physical-chemical conditions of the substrate (humidity, temperature, salinity, etc.), infection by pathogens such as bacteria or fungi, and predation by various vertebrates and invertebrates (Acuña 1980; Moll & Legler 1971; Pritchard et al. 1984; Dodd 1988). Invertebrate predators include crabs (Márquez et al. 1976), ants (Hughes 1974; Witherington 1986), and fly larvae.

Fly larvae have been reported from eggs of *Malaclemmys terrapin* (Aldrich 1916), *Trionyx muticus* (Muller 1921), *Graptemys pseudogeographica* (Vogt 1981), and *Lepidochelys olivacea* (Polimeni 1988). The flies in these cases were all Sarcophagidae. Manuel Benitez (pers. comm.) has found unidentified fly larvae in decomposing eggs of *Caretta caretta* buried 30-40 cm below the soil in El Salvador. Two species of flies of the family Phoridae have been reported from eggs of *Pseudemys scripta* in Panama (Moll & Legler 1971). We report here the presence of one of these species of Phoridae from eggs of *Rhinoclemmys pulcherrima.*

From a natural nest found in March 1988 in the city of Puntarenas (Puntarenas Province), Costa Rica, six eggs of *Rhinoclemmys pulcherrima* were placed in an incubator in which the temperature was maintained at 28° C. The eggs were partially buried in sterilized soil. After 113 days in the incubator, three of the eggs became darker and appeared to have stopped developing. One of these

three eggs was dissected and was found to contain fly larvae. The remaining two eggs were then transferred to a cage covered with fine mesh cloth. Within one week adult flies emerged from these two eggs. The other three eggs from the nest hatched normally.

Some of the flies emerging from the original two eggs were transferred to bottles containing a nutrient medium composed of agar (4 g), banana (100 g), dry active yeast (a few grains), propionic acid (2 g), and water (95 ml). The remaining flies were left in contact with the decomposing eggs where another generation was completed. These flies from the second generation, having exhausted their food supply of decomposing eggs, were then placed in bottles with nutrient media. The cage containing the emerged flies was cleaned and supplied with two fresh eggs from a captive (unmated) turtle of the same species. The eggs were first washed in water and were then partially buried in autoclaved soil and held at ambient temperature (18-26° C); a fine mist of water was applied to the soil every four days in order to avoid dehydration.

The flies reproduced very well on the nutrient media and apparently interbred with those of the second generation from the original field collected turtle eggs. The eggs from the captive turtle were readily attacked and adult flies emerged in ca. two weeks.

The flies were identified as a species of Phoridae, *Megaselia scalaris* (Loew) (identification by Brian Brown, University of Alberta). This species is extremely polyphagous, having been previously reported from various insect hosts (especially insects in culture), rotting plant tissue, feces, and as a cause of human myiasis (Robinson 1971). *Megaselia scalaris* has also been reared from viable frog eggs: a phyllomedusine in Costa Rica and a leptodactylid in Puerto Rico (Villa & Townsend 1983). We have encountered only one previous record of *M. scalaris* from turtle eggs (Moll & Legler 1971).

When turtle eggs are transferred from the field to the laboratory many of the eggs are frequently found to be infected by bacteria or fungus (Acuña 1980; Wyneken et al. 1988). It is possible that *M. scalaris* locates turtle eggs, in the field as well as in the laboratory, by means of odor from rotting eggs. Nonetheless, when flies were placed with fresh eggs from the captive turtle they demonstrated no difficulties in locating the turtle eggs. Another possible source of attractant for the flies is the cloacal secretions that have been observed in *R. pulcherrima* during deposition of eggs (Monge-Nájera et al. 1988). These cloacal secretions may not have been removed by simple washing in water. Eggs of *Pseudemys scripta* are reported to be most vulnerable during hatching but this was not the case in *R. pulcherrima.*

The adult females of *M. scalaris* oviposited on the surface of the captive turtle eggs and in the soil covering the eggs. Studies of the ultrastucture of the egg shell of *R. pulcherrima* have demonstrated the existence of pores ranging in size from 100 to 700 micrometers (Acuña 1987). Newly hatched larvae of *M. scalaris* were found to have a maximum diameter of 470 micrometers and are therefore quite capable of entering the eggs through larger pores. Once inside the shell the fly larvae probably utilize proteolytic enzymes to break through the egg membrane. Larval feeding within the egg causes the egg to become dehydrated, which in turn results in shell breakage. Flies were observed pupating within the egg and adults probably depend upon shell breakage for emergence from the egg.

Megaselia scalaris is certainly one of the most polyphagous of all insects, attacking a wide range of rotting materials as well as nonrotting but defenseless meat. In the case of turtles this fly appears to be capable of attacking both developing eggs (Moll & Legler 1971) and non-developing eggs (our results). Further study is needed to determine its role as a mortality agent of turtle eggs under natural conditions and whether rates of attack differ between turtle species.

ACKNOWLEDGMENTS

We would like to thank Vilma Castillo Centeno for her enthusiasm in stimulating this study, Bernal Badilla V. for constructing the screen cages, Rafael Hernández for helping in the preparation of the media, and Brian Brown for the identification of the flies.

GEOGRAPHIC VARIATION IN THE EGG-LAYING STRATEGY OF THE MOLE SALAMANDER, *Ambystoma talpoideum*

There have been several conflicting reports on the egg-laying strategy of the mole salamander, *Ambystoma talpoideum* (Bishop 1943; Mosimann and Uzzell 1952; Shoop 1960; Semlitsch 1985; Semlitsch et al. 1988). Two distinct types of egg-laying patterns have been reported. The first, described by Bishop (1943) for Mississippi and Louisiana, Mosimann and Uzzell (1952) for South Carolina, and Shoop (1960) for Louisiana, indicates that females oviposit small, fragile clusters of eggs (4-41) on twigs, sticks, or grass stems. Shoop (1960) noted that often many clusters appear on the same twig, and may or may not be laid by the same female. The second, described by Semlitsch (1985), indicated that South Carolina females haphazardly scatter their eggs singly across the pond bottom on debris, leaves, and twigs (Fig. 1). A. Braswell (pers. comm.) has also noted this single-egg-laying strategy for North Carolina females. At least three explanations are possible for these observations: 1) one or more of the observations are erroneous, 2) *A. talpoideum* constitutes two cryptic species, each displaying a different strategy, or 3) this species has two distinct egg-laying strategies which vary geographically.

Although widely separated populations are differentiated, no present evidence suggests

two cryptic species within *A. talpoideum* (Lowcock, pers. comm.). Larvae from the Mississippi Valley Physiographic Province (Oktibbeha Co., MS and Shelby Co., TN), however, are distinctly different in pigmentation pattern from individuals found in the Atlantic Coastal Plain Physiographic Province (Union Co., NC; Aiken, Allendale, Barnwell, Charleston, Hampton, Orangeburg, and Sumter Counties, SC; Semlitsch, pers. obs.). Further detailed systematic biochemical and morphological studies of geographic variation are clearly needed to fully eliminate this possible explanation.

One of the reports of *A. talpoideum* egg-laying appears erroneous. Mosimann and Uzzell (1952) reported finding seven masses containing 10-41 eggs and nine adult *A. talpoideum* in a small pond in Dorchester Co., SC. Their report, however, is based on indirect evidence; neither did they observe directly *A. talpoideum* ovipositing nor did they rear larvae from those eggs to metamorphosis. Indeed, *A. talpoideum* is abundant in Charleston Co., SC and one of us (RDS) has found numerous ponds with single eggs presumably laid by *A. talpoideum* and also egg masses presumably laid by *A. tigrinum*. Larvae reared from similar egg masses collected in Aiken Co., SC have been identified as *A. tigrinum*. The single eggs, attached to decaying leaves, could easily have been overlooked if we had been "expecting" egg masses such as previous reports described. The egg masses of *A. tigrinum* in South Carolina have a similar appearance and contain a similar number of eggs (24-98) as do *A. talpoideum* egg masses reported from Mississippi and Louisiana. The egg masses of *A. tigrinum* in South Carolina, however, have a much thinner and "softer" external envelope than do those of *A. maculatum*, which Mosimann and Uzzell (1952) used for the comparative basis of their identification. Mosimann and Uzzell (1952) present the only early description of *A. talpoideum* eggs from the southeastern Atlantic Coastal Plain and we believe the eggs were identified incorrectly. Moreover, all other earlier descriptions of *A. talpoideum* eggs are from southern Mississippi or Louisiana (Bishop 1943), where *A. tigrinum* is altogether absent or rare (Dundee 1988; R. Altig pers. comm.).

Finally, we believe that *A. talpoideum* does exhibit two different egg-laying strategies: oviposition of single eggs on the Atlantic Coastal Plain and egg masses in the Mississippi Valley Physiographic Province. We have reared larvae to metamorphosis from eggs of both types (masses and single) from several natural ponds in both regions that, unquestionably, are *A. talpoideum* (preserved specimens are available for examination). In 10 years of study, South Carolina *A. talpoideum* females (both metamorphic and paedomorphic) have only oviposited eggs singly in natural habitats, dishpans, plastic wading pools, and cattle tanks. Masses have never been observed.

We believe that this variable egg-laying strategy of *A. talpoideum* is unique among salamanders and has gone undetected for years because of the difficulty of finding single eggs in natural ponds and expectations of finding egg masses. We know of no other salamander that is capable of variable egg-laying and suggest that a study of this species' geographic distribution, environmental advantage (e.g., predation and desiccation resistance), and evolutionary significance would be informative.

ACKNOWLEDGMENTS

We thank A. Braswell, J.W. Gibbons, M. Jackson, T. Lamb, J. Pechmann, and C.R. Shoop for comments on this manuscript and R. Altig and L. Lowcock for their information.

TECHNIQUE

A NEW PROCEDURE FOR DERMESTID BEETLE PREPARATION OF SKELETONS FROM FORMALIN-FIXED SPECIMENS

Dermestid beetles (Coleoptera: Dermestidae) have long been used to prepare vertebrate skeletons (e.g. Hildebrand 1968). Fixed specimens (those either fixed in formalin, stored in 70% ethanol, or both) are difficult or impossible to skeletonize using standard dermestid techniques. Attempts to make these specimens more palatable to dermestids include application of beef fat or bacon grease (De La Torre 1951) or cod liver oil (Hooper 1956). In our experience dermestids stop feeding once the superficial layer of grease is removed and the process must be repeated. Alternatives to dermestid cleaning (maceration, hand cleaning) are time and labor intensive and usually do not produce skeletons of equivalent quality.

While preparing large series of skeletons from both fixed and fresh reptile specimens, we have found a method yielding far better results than any others we have tried. The only material needed for treatment is fresh muscle tissue or blood. The procedure is as follows.

1. Fixed specimens (to be skeletonized) are skinned, eviscerated, and soaked in cold or room temperature tap water for 1-3 days, depending upon body mass. Water changes may be made, but do not appear necessary.
2. A "blood solution" is prepared. A fresh specimen is soaked in a container of cold tap water until the water is full of blood and body fluids. It is useful to make one or more large incisions to allow the fluids to leave the body. A ratio of ca. 5:1 (body volume: water volume) works well. If the specimen is frozen it may remain soaking until thawed (overnight or longer for large specimens).
3. The fixed specimen is then soaked in this "blood solution" for 3-14 days (depending largely on body mass) at room temperature. It is then removed, excess blood removed by blotting or air drying, and the damp specimen placed in the dermestid colony. It is not recommended that it be placed in the colony while very wet, unless it is of a size that can be cleaned in one day or so, as dampness tends

to promote mold. Depending upon the condition of the dermestid colony, it may also help to remove all other food sources while the fixed specimen is present.

In some cases the dermestids do not completely clean the specimens. Even repeating the blood soaking procedure as many as six or seven times with a single specimen was usually more efficient and quicker than using cod liver oil or grease. In many cases specimens were completely cleaned after one blood soaking. This was rarely the case with other treatments.

This procedure does not require a fresh cadaver as a blood source each time. We have had excellent results by saving pieces of muscle tissue whenever fresh reptiles (e.g. zoo or pet shop specimens) were available. We have successfully used pieces that had been stored frozen for at least four years. Frozen muscle pieces from any fresh cadavers could readily be stockpiled for future use. This method might work with mammalian muscle and blood (e.g. from butcher shops) but we have not tried this.

Many variables may affect the success of this procedure, including concentrations and amount of fixative, length of time stored in fixative or preservative, and buffers present. These factors were unknown in nearly all the specimens that we prepared. We could not ascribe the observed variation in our results of these factors. We believe that extreme precision in temperatures, times or volumes used is not critical. Larger specimens tend to take more time for each step of the process than do smaller ones.

We have not had any major problems with this procedure. The odor produced by an extended blood soaking is comparable to that produced by maceration, so that adequate ventilation is required. We have not observed bone discoloration known to be due solely to this procedure. Many of our fixed specimens were noted during the skinning process to have discolored bones and we suspect that much of this is due to the action of the fixative. In any case, discoloration would seem a small price to pay for an otherwise clean skeletal preparation. We have not tested this method with terrestrial isopods (Maiorana dn Van Valen 1985).

HERPETOLOGICAL HUSBANDRY

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and speciman manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

REPRODUCTION IN THE PANCAKE TORTOISE, *Malacochersus tornieri*, IN CAPTIVE COLLECTIONS

The pancake tortoise has long been of interest to zoos and collectors, yet captive reproduction in this species is still sporadic and fortuitous. This paper will report on the breeding activity in two *Malacochersus tornieri* collections in the Washington, D.C. area, and review the published literature on the subject.

The National Zoological Park (NZP) acquired its first female pancake tortoise, which is still in the collection, in May 1965, but did not add any males until April 1972. Since then the collection has fluctuated considerably, from 1.2 to 4.7 adults housed in one or more groups, but has typically consisted of 1.3 adults in one exhibit. NZP presently has 3.6 adults in two separate groups.

The private collection of Anne F. Darlington (AFD) consists of 1.1 adults acquired as subadults in March 1986 and a subadult female added in February 1988.

HUSBANDRY

Caging and environment. Housing of the NZP animals has varied but usually they have been maintained as a group in an indoor exhibit similar to the current one. This is a 2.5x2.5 m enclosure with a 50/50 sand and potting soil substrate, and rockwork around the periphery forming crevices for the specimens and planters for live *Euphorbia* and *Sansevieria*. An 80 watt fluorescent fixture positioned 2.5 m above the substrate is set to give 12 h of illumination in summer and 9 h in winter. Skylights provide supplemental sunlight. Daylength at this 39° N latitude is 15 h in June and 9.5 h in December. The mean ambient cage temperature is 28.5° C, with an average daily fluctuation of 5.3° C. A 30x100 cm heating pad buried 5 cm under the substrate provides a hot spot exceeding 40° C. A water bowl is always available.

NZP specimens maintained off-exhibit are kept in a 1.2 m square plywood box with wooden hideboxes. A year-round 12 h daylength is produced by an 80 watt broadspectrum fluorescent fixture suspended 75 cm above the substrate of crushed oyster shell. The ambient temperature averages ca. 28° C and is supplemented by a 250 watt infrared heat lamp which produces an area over 40° C. These specimens are placed in a pan of water three times a week.

The AFD collection is housed outdoors in the Washington, D.C. area when the weather permits. This typically means the tortoises are outdoors continuously from mid-June to mid-September but only during warm, dry, daylight hours in the spring and fall. The enclosure is a fenced 2.5x3 m area of grass with wooden and terra cotta pipe hideboxes, and a pan of water. Other tortoise species also occupy the pen.

When indoors, the AFD *M. tornieri* are housed in a 1.5x2 m cage with wooden hideboxes. A 12 h photoperiod is provided by an 80 watt broadspectrum fluorescent fixture 35 cm above the oyster shell substrate. The ambient temperature averages 24° C during the day and 20° C at night, with a heating pad on continuously at over 42° C. Twice a week the tortoises are placed in pans of water. When nesting is anticipated, a pan of slightly moistened, hard-packed soil is placed in the cage.

Diet. The NZP pancake tortoises receive the Reptile House's herbivore diet. Until 1985, this was a salad of vegetables and fruits, supplemented with canned dog food and a vitamin and mineral powder, but since then it has consisted of alfalfa hay with soaked dry dog food, some vegetables, fruits, and supplements. The adults are fed twice a week. The AFD collection is fed mostly greens with some vegetables and a small amount of fruit, at least four times a week. When outdoors the tortoises can graze freely, but rarely do so.

COURTSHIP AND AGGRESSIVE BEHAVIOR

Season. Courtship in the NZP collection is seen year-round at a low level of frequency. The AFD male typically only courts while outdoors, but then does so one or more times a week. Grimpe (pers. com.) reports that courtship is so common at all times of year at the Tulsa Zoological Park (TZP) that the sexes are periodically separated to reduce the stress on the females.

Courtship behavior. At NZP, a male typically chases a female and mounts from behind, extending his front legs so that his body is nearly vertical. While mounted, the male either gapes or fully opens and closes his mouth at intervals of ca. one sec, without distinct vocalization. Males have occasionally been seen biting females on the neck. The AFD male courts the adult female in the same manner, without any biting. However, his

behavior with the subadult female has included additional sequences. On several occasions, he circled the subadult female and systematically bit each of her appendages. When he climbed atop her, instead of assuming the copulatory mount he remained horizontal, holding her down with his body, biting and scraping with his forelegs at her head and forelimbs to keep her retracted. He kept her thus immobilized for as long as 10 min and then left without attempting copulation. On other occasions, he chased, mounted and copulated with the subadult female as with the adult, without biting or otherwise attempting to immobilize her.

Loveridge and Williams (1957) describe male pancake tortoises viciously biting the females during courtship, even gripping and dragging them by their marginals. Wilke (1983), however, refers only to chasing and copulation.

During the summer of 1988 the AFD male was seen chasing a juvenile *Geochelone carbonaria* on several occasions. Loveridge and Williams (1957) relate that a male repeatedly attempted to mate with a *Kinixys b. belliana.*

Size at maturity. The AFD male was acquired at 117 mm CL and 165 g mass, and first displayed courtship behavior at 124 mm CL and 213 g. Both females were ca. 130 mm CL, 250 g when the male began to court them, and the adult female was 145 mm CL and 400 g at her initial oviposition. An NZP male raised from a hatchling commenced courtship upon being introduced to the group at 115 mm CL, 215 g, when he was 3.5 years old, but was sexed a year earlier.

Aggression. In the first six months after introduction, this same NZP male made five attacks upon another male in the group, who had to be separated permanently. These generally consisted of bites to the hind legs, but on one occasion the aggressor had overturned the other male and was found standing on him, biting his limbs. The victim is blind from cataracts, which may have been a causal factor. No other incidents of male-male aggression have been observed, though both these males have been housed for extended periods in mixed-sex groups.

Beattie (1971), however, relates a similar case of an adult male repeatedly ramming and biting a juvenile one, and also describes an adult female initially showing aggression toward this juvenile "to establish pecking order." When the AFD subadult female was first introduced to the pair, the male immediately approached and sat for several minutes with his snout and front marginals actually touching hers. This was interpreted by the observer, perhaps anthropomorphically, as an act of intimidation. In the aggregate, these incidents suggest that groups of *M. tornieri* may form dominance hierarchies which could have an impact on the success of breeding programs. Additional observations are required, however, before the existence, strength, and nature of such hierarchies can be determined.

EGG LAYING

Season. Eggs have been found in all months of the year except February at NZP, with a slightly greater concentration from November through January. The AFD female has laid from October through January. Wilke (1983) gives a July to November nesting season, and Grimpe (pers. com.) a September to January one, though eggs have been laid at NZP through the winter to May. Shaw (1970) reports egg production throughout the year, with a somewhat higher level from September through December.

Gravidity. Gestation has not been determined for either collection, but the relative periods of breeding and laying of the AFD pair imply a period of at least 60 days. Observation of nesting behavior is the first indication in either collection that a female is gravid. Experience to date indicates that palpation is not successful in *M. tornieri,* since no eggs have ever been felt, even when a female was palpated only a few days before laying.

False-nesting. At NZP, pancake tortoises have repeatedly been observed digging nests without eggs later being found. Gyarmaty (1988) also observed that several days of nesting behavior precedes oviposition. The AFD female engaged in two-to-four days of false-nesting before each of the first season's clutches, typically while remaining in the hidebox, and was twice seen digging the day after laying. No observations were made of the November 1988 clutch. In January 1989, the AFD female was observed digging nests on nine of eleven consecutive days, and so was given oxytocin. After laying an egg on the surface of the soil, she vigorously made covering motions with her hind legs for 10 minutes. Later that day and the following afternoon she was again observed making covering motions.

Nesting. All the AFD nesting behavior has occurred in the mid- to late afternoon. Most occurs at the same time of day at NZP, but some early morning and evening nesting also takes place. The female seems to prefer a very warm, well-lit location for the nest, and tips her head down and touches her chin to the soil before commencing. The nests are dug with the alternating rear leg movements typical of other tortoise species (Obst 1986), except the female does not urinate on the soil before or during digging. The completed nests are 6-9 cm deep, and the elongated eggs are placed horizontally. Also, at NZP eggs are often partially buried or left exposed on the surface, even when a seemingly suitable area for nesting is available.

Clutch characteristics. The AFD female laid four clutches in the 1987 season and two the following season. The first season the intervals averaged 28 days with a range of 27 to 29 days. Her second season, the interval was 45 days, but the second oviposition was induced with oxytocin. *M. tornieri* in the collection at TZP range from one to six clutches/yr/female (Grimpe, pers. com.), and Wilke (1983) reports one to four. Both sources indicate the shortest clutch interval as 23 days, and that the intervals would average ca. 40 days. Since it is not always possible when an egg is found at NZP to identify which female laid it, the number of clutches/yr/female or the interval cannot be determined. However, one season there were 12 eggs from five females, indicating an average of up to 2.4 eggs/female. This is consistent with the 19 eggs from seven or eight females in 1966 reported by Shaw (1970), and the three clutches/yr/female given by Obst (1986).

In November of 1988 the AFD female laid a clutch of two eggs. Two egg clutches have also been reported by Grimpe (pers. com.) and Gyarmaty (1988), but have not been recorded at NZP.

EGGS AND INCUBATION

Fertility and hatch rates. Three of the seven AFD eggs hatched (43%), one fertile egg spoiled (14%), two were infertile, and one is currently incubating. Four of the NZP eggs have hatched (6%), four were fertile but died in the egg, 11 were found broken (17%), and 46 were presumed infertile (71%). Low fertility and hatch rates seem common in captive *M. tornieri.* Wilke (1983) obtained 15 hatchlings from 23 eggs (65%), and Shaw (1970) had 31 of 76 hatch (41%). Grimpe (pers. com.) reports that of 52 eggs, seven hatched (13%), two died in the egg (4%), 35 were infertile (67%), four were found broken (8%) and four are now incubating.

Incubation methods and times. The NZP incubation method has varied over the years. The first hatchling, in 1978, incubated in the exhibit subtrate. Two others were from eggs artificially incubated in covered 10 gal aquariums heated with plumber's heat tape. The eggs were partially buried in dampened potting soil in plastic containers. The containers were placed in the aquarium on a layer of pea gravel and a relatively high humidity was maintained by adding water to the gravel. The mean temperature of this setup was 26.7° C (range 25.0°-30.2° C). The most recent hatchling was set up in a human incubator with a mean temperature of 30.8° C (range 29.0°-33.8° C) and moderate humidity. The incubation periods (to pipping) for the first two were 169 and 237 days, but the eggs may not have been found immediately after they were laid. The last was 99 days, and the egg was definitely found on the day of deposition.

The AFD eggs were maintained in a poultry incubator which was set for 30° C (range 24-34° C). The eggs were placed on a mixture of sand and peat moss which was kept moderately dry. Incubation times (to emergence) were 177, 184 and 188 days. Wilke (1983) reports incubation times of 117 to 188 days, with a mean of 147, at 28° C and 95% R.H., and Grimpe (pers. com.) gives incubation times of 122, 167 and 187 days at 26-30° C. Shaw (1970) reports a mean of 178 days for 28 eggs, ranging from 113 to 221 days, using various incubation methods with temperatures fluctuating between 26 and 35° C.

HATCHLINGS

Size. As the embryo completes development, the carapace width is oriented along the length of the egg. To fit within the narrow diameter of the egg, the carapace length is reduced considerably by a deep fold across the plastron. Thus when the hatchling first emerges it is highly bowed, and significantly wider than it is long. When the plastron has flattened, after about 24 h, the hatchling becomes nearly circular and the carapace is only moderately domed. See Table 1 for egg

and hatchling dimensions.

Husbandry. Both the NZP and AFD young are treated the same as the adults with regard to diet, environmental conditions and provision of water and hideboxes, except that they are fed four or more times per week and their food is finely chopped. They share the same strongly herbivorous dietary preferences as their parents. Their response to water is also as individually variable as in the adults. They have been maintained on an oyster shell substrate, housed in a variety of containers which are secure against their abilities to climb and squeeze through narrow cracks.

Growth. Hatchlings in both collections have quadrupled their weight by seven months old and doubled their carapace lengths by nine months of age. Wilke (1983) reports even faster gains. Gender identification may be possible at two to three years of age under captive conditions. Grimpe (pers. com.) reports that the first two TZP hatchlings were sexed as males by tail size and observations of mounting at three years old, though they were not responsible for fertile eggs until five years of age. An NZP male was first sexed at about two years, six months old.

Survival rates. Mortality in the hatchlings varies but is commonly low. Of the four NZP hatches, a one-year-old juvenile and a nine-year-old male survive, a five-year-old female died of pneumonia, and a two-year-old juvenile died of intestinal impaction. The AFD hatchlings are only one year old or less, but doing well. Wilke (1983) and Grimpe (pers. com.) both have 100% survival rates (four and seven years, respectively) after their first hatches. Shaw (1970), however, reports only 10 of 31 hatchlings (32%) still alive at the end of the 10 year period covered.

DISCUSSION

Clearly the reproductive potential of *M. tornieri* is greater than implied by the one egg per season reported in the early literature (Loveridge and Williams 1957). However, the fertility and hatch rates in existing collections are too low for that potential to be realized. This may be due to the lack of some or all of the necessary environmental cues in captivity that control the breeding season. Alternatively there may be a genetic incompatibility of the individual specimens. *M. tornieri* has a discontinuous distribution, with isolated populations occurring only in rocky terrain where suitable cover is available (Eglis 1967). Thus it is possible that there is sufficient genetic disparity to result in reduced viability of offspring if the parents came from different areas. In addition, some as yet unidentified problem with diet, husbandry or incubation methods may be reducing the rate of reproduction. At present, no conclusions can be drawn from the data available, and further study is required to resolve the issue.

ACKNOWLEDGMENTS

We would like to give special thanks to Rusty Grimpe, Reptile Curator, Tulsa Zoological Park, for his generous provision of data, and to Dale Marcellini, Curator of Herpetology, National Zoological Park, for editing the manuscript.

LIFE HISTORY NOTES

Life History Notes is analogous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which best describes the nature of their note (e.g., Reproduction, Longevity, Morphology, etc.). Figures are permissible to illustrate any data, but should **replace** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose! Articles submitted to this section will be reviewed and edited prior to acceptance.

Standard format for this section is as follows: SCIENTIFIC NAME (in caps), COMMON NAME (in parentheses) as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles,** (Second edition, Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), KEYWORD (in caps). DATA on the animal (one, or at **most** two, references may be ***briefly*** cited in text—***DO NOT*** include complete literature reviews—use summary articles wherever possible). Place of deposition or intended deposition of specimen(s), and catalog number(s). Then, skip a line and close with SUBMITTED BY (Name(s) in caps, and address(es) in full—no abbreviations).

(NCN) used for common name = no recognized common name.

Recommended citation for articles appearing in this section is as for Geographic Distribution.

ANURA

ELACHISTOCLEIS BICOLOR. **AMPLEXUS BEHAVIOR.** On 25 November 1987 a pair of *E. bicolor* was observed in amplexus at Roque Saenz Pena (26° 47' S - 60° 27' W), Chaco, Argentina. Axillary amplexus was observed in open water; the male was glued to the back of the female by a secretion produced by a glandular area of the male's chest behind the axilla. Externally, the glandular area appears as a porous, slightly darker pigmented area of skin that covers ca. 17-20% of the ventral surface. The secretion is strong enough to keep the frogs bonded together after placement in chloretone. The natural process of detachment is unknown. The specimens were deposited in the collection of the Fundacion Miguel Lillo, Tucuman, Argentina (FML 04357).

CERATOPHRYS CRANWELLI (Escuerzo). **OVIPOSITION.** On 28-30 October 1985, oviposition in *C. cranwelli* was observed at Monte Quemado (25° 28'S- 62° 52' W) Santiago del Estero, Argentina. Males called from open areas on the margins of a pond; amplexus occurred in shallow water. During amplexus the frogs swam slowly on the surface, then dived suddenly, spraying ca. 25 eggs into the water when the cloacas were nearly perpendicular to the surface.

During oviposition the female produced a series of lateral movements with the femurs,

after which the pair returned to the surface, moved forward 3-5 m, and repeated the process several times during the same night. The eggs floated for a couple of minutes, then scattered individually as they sank slowly to the muddy bottom.

As tadpoles of this species are carnivorous and sedentary, we infer that this behavior results in a selective advantage that reduces fraternal cannibalism. Voucher specimens (FML 03635) were deposited in the collection of the Fundacion Miguel Lillo, Tucuman, Argentina.

CAUDATA

PLETHODON DORSALIS (Zigzag Salamander). **MASS MOVEMENT.** Mass movements such as breeding migrations have been well documented in aquatic-breeding terrestrial salamanders in the families Ambystomatidae (Peckham and Dineen 1955. Proc. Indiana Acad. Sci. 6:278-280; Semlitsch 1985. Copeia 2:477-489), Salamandridae (Hurlbert 1969. Ecol. Monogr. 39:465-488), and Plethodontidae (Semlitsch and McMillan 1980. Brimleyana 3:97-105). Breeding migrations are unknown in plethodontid salamanders that lay eggs on land as reproductive activities occur within the normal home ranges of individuals (Duellman and Trueb 1986. Biology of Amphibians. McGraw Hill, New York 670 pp.). However, vertical and horizontal movement related to moisture level has been observed in *Plethodon cinereus* (Heatwole 1962. Ecology 43:460-472; Smith 1961. The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Survey, Urbana 298 pp.).

On the evening of 21 February 1981 I observed a mass unidirectional movement of *Plethodon dorsalis* in the LaRue-Pine Hills Ecological Area of the Shawnee National Forest in Union County IL. While driving on F.R. 345 between the face of the Pine Hills bluff and LaRue swamp (T11S, R3W, Sec 16 and Sec 9) just after sunset during a brief but heavy rain, I encountered roughly 100 salamanders crossing the road. All but one were descending from the bluff toward the swamp.

Southern Illinois experienced a drought in 1980, with total precipitation recorded at Cairo, IL (ca. 70 km SE of site) 28% below the 1941-1970 30-year mean (NOAA 1980. Climatological Data, National Summary 31[1-13]). Whereas January 1981 was also abnormally dry, with precipitation 91% below average, February 1981 was only 5% below normal (USDA 1981. Weekly Weather and Crop Bulletin 68[1-8]).

It appears that this mass movement of salamanders was in response to a period of increased moisture during the drought. *Plethodon cinereus* is less mobile and forages less efficiently during dry periods (Jaeger 1972. Ecology 53:535-546). Movement to a site that retains moisture (such as the vicinity of the swamp) may allow salamanders to continue to forage efficiently during dry periods.

I wish to thank Geri Hawley, Thomas Locke, and Gail Nachel for assistance in removing salamanders from the road, and Dale R. Jakson for commenting on the manuscript.

TESTUDINES

CHELYDRA SERPENTINA (Common Snapping Turtle). **FEEDING BEHAVIOR.** Snapping turtles are particularly catholic in food selection. Nevertheless, the near exclusive diet of duckweed (*Lemna)* by a large (32.8 cm CL) male from Lake Co. Illinois seems worthy of note. In a biotelemetry study of turtles at Chain O'Lakes State Park, this turtle was observed feeding at the surface of a duckweed covered pond on ten occasions between 23 May and 3 August 1988. Feeding times ranged from 1250 h to 1655 h with pond temperatures (10 cm depth) varying from 19° to 34° (mean 29°) C. Although the dense duckweed obscured details of the feeding process, the turtle appeared to be using neustophagia (Belkin and Gans 1968. Ecology 49:768-769). Periodically raising the head just above the surface, the animal would then open and close its jaws several times in succession. After foraging for 1 to 10 min in a small area (ca. 1 m^2), it would move several meters and repeat the procedure.

The turtle was hand-captured and fecal samples were obtained on May 23, 29, and June 13. On July 26 the stomach was flushed (Legler 1977. Herpetologica 33:281-284). Composition of the 45 ml of feces collected was *Lemna* 92%, other plants 6%, and animal remains (insect, mollusks, amphibian bones) 2%. Composition of 50 ml of regurgitate from the flush was *Lemna* 95.5%, vascular plants 2%, and animal matter (snails and fish) 2.5%.

Lemna has been previously reported in snapping turtle diets but not as a staple (Ernst and Barbour 1972. Turtles of the United States. The University Press of Kentucky, Lexington, p. 24). Diets of 21 other snapping turtles collected at the site comprised ca. equal amounts of plant and animal material but no other individual had consumed more than trace amounts of duckweed. Fish was the most important animal food occurring in 38% of the samples and comprising 24% of the total volume consumed.

HYDROMEDUSA MAXIMILIANI. **ECOLOGY.** *H. maximiliani* has a wide distribution in SE Brazil, ranging from Espiritu Santo (20° S) to Sao Paulo (Luderwaldt 1926. Rev. Museo Paulista 14:403-468). Virtually nothing has been published about the ecology of this species.

On 7 and 12 November 1988, 15 active individuals (2.10.3) were observed in a 1 km section of a small rocky stream 1-3 m wide in a subtropical rain forest at 900 m elevation in the Carlos Botelho State Reserve (24°03'S; 47°59'W) (water pH = 7.9, water temperature = 16-18° C, air temperature = 16-20.5° C). The cloacal temperature of the turtles ranged from 16°-20.0° C, $\bar{X}$ = 18.7° C; N = 12. The temperature of an individual captured while basking on a stone in a small patch of sunlight was 19° C. The body temperatures recorded for active *H. maximiliani* are the lowest recorded for a neotropical turtle, and only comparable to some Emydids (Brattstrom 1965. Amer. Midland Nat. 73:376-422).

The shells of adult *H. maximiliani* have a cryptic shape similar to that of a dead leaf (the carapace in juveniles is saw-toothed and lighter in color); the turtles rest at curves in the stream where dead leaves accumulate. Low light levels in the forest make the turtles very cryptic in these microhabitats.

Feces were examined from five newly-captured turtles and included remains of several insect orders: Coleoptera; Isoptera; Hemiptera; and Neuroptera as well as several unidentified insect larvae. The decapod crustacean *Aegla odebrechi* was the most common food item found in feces. No vertebrate remains were found in feces; grains of quartz and plant fibers found in the feces were probably taken incidentally. A female captured in November 1988 laid three 40 x 25 mm eggs in January 1989.

I thank S. Pacagnella for logistical support during this study. A.S. Abe and W. Magnuson provided comments on the first draft of the manuscript.

LEPIDOCHELYS KEMPI (Kemp's Ridley Sea Turtle). **REPRODUCTION.** Kemp's ridley, the most endangered of the world's sea turtles, has a highly restricted nesting distribution. Approximately 95% of the nesting population emerges on a single 32 km beach (Rancho Nuevo) in Tamaulipas, Mexico. Only a small number of nesting records exist for localities elsewhere in Mexico and in Texas; there is one unconfirmed report from Colombia (Ross et al. 1989. The status of Kemp's Ridley, Report to the Center for Marine Conservation, Washington, DC, 51 pp.).

On 30 May 1989 at 0930 h EST, a Kemp's ridley nested on Florida's west coast at Madeira Beach (27° 47' N; 82° 48' W, Pinellas Co., 146th Ave. and Gulf Blvd.). This represents the first documented nesting of *Lepidochelys kempi* in Florida. Although this species is regularly recorded along Florida's west coast, most of these animals have carapace lengths that indicate that they are immature (Ogren, L. 1989. Pp. 116-123, Proc. First Int'l. Sympos. on Kemp's Ridley Sea Turtle Biology, Conservation. and Mgmt. [C. Caillouet and A. Landry, eds.]. Texas A&M Univ. Seagrass Program [TAMU-SG-89-105]).

The ridley deposited 116 eggs, which is a normal complement for this species; daytime nesting is also typical. The nest was inundated by storm tides on 6 June and relocated within a few hours to higher ground. Eighteen hatchlings emerged at dawn on 27 July, and an additional 6 on 28 July, after incubation periods of 58 and 59 days, respectively. Several hatchlings that died in the nest have been deposited in the American Museum of Natural History (AMNH 135224-27).

The nest site was on a highly developed stretch of coast, with high-rise condominiums and a seawall immediately adjacent. Dozens of tourists witnessed the turtle's emergence and nesting. A videotape of the

nesting sequence is archived at the Florida Marine Research Institute.

An attempted nesting by a second Kemp's ridley was recorded that same month on the east coast of Florida. On 22 May 1989 (1150 h EST), a ridley emerged at Phipps Ocean Park, in Palm Beach (Palm Beach Co., 4 km north of Lake Worth Bridge). The turtle excavated a nesting chamber but did not deposit eggs. A second sighting of what was presumed to be the same turtle was made by JF on 5/30; crawls observed in the same vicinity on 5/23 and 5/31 are also attributed to this animal. No eggs were deposited during any emergence, as far as is known. A photograph of this ridley taken by JF on 22 May 1989 is archived at the Florida Marine Research Institute. Neither the west coast nor the east coast ridley was tagged.

Submitted by **ANNE MEYLAN, PATRICIA CASTANEDA,** and **COLLEEN COOGAN,** Florida Marine Research Institute, 100 8th Avenue, S.E., St. Petersburg, FL 33701; **TONY LOZON,** Florida Environmental Preservation Association, 78 146th Ave., Madeira, FL 33708; and **JOHN FLETEMEYER,** Town of Palm Beach, P.O. 2029, Palm Beach, FL 33480, USA

***LACERTA PARVA*. COURTSHIP AND REPRODUCTION.** The sexual behavior of this species is as yet undescribed. Only some morphometrical statistics on preserved animals—including eggs and young—are available (Peters, G. 1962. Die Zwergeidechse (*Lacerta parva* Blgr.) and ihre Verwandtschaftsbeziehungen insbesondere zur Libanon-eidechse (*Lacerta fraasii* Lehrs). Zool. Jahrb. Syst. Jena 89:407-478).

Three wild-caught animals (2.1) were obtained from a dealer in June 1987. Animals were housed in a 50x30x30 cm glass terrarium, with a layer of sand, some rocks and branches. It was heated by a 25W spotlight for 5-8 h/day (increasing with the natural daylength) resulting in ground temperatures of 15-35° C ($\bar{X}\cong$ 18° C.).

After hibernation at 3-5° C from 5 December 1987 to 17 January 1988, 21 matings of these four lizards were observed from 4 February to 30 April 1988. The male approached the female and secured a mouthgrip on the side of her tail or body. Save for a few forward steps, receptive females remained passive. In 20.5±9.5 (5-44) seconds [$\bar{X}$±S.D. (range)] the male reached, by quick snapping movements, a position just before her hind legs. He then curled his body as she raised her tail base and they copulated.

Just after intromission was achieved, the male bit the female's femur and within one or two seconds relocated his grip to the fibulatibia of the same leg (Fig. 1). Rarely the femur bite was skipped. While *in copula,* one or two of the male's front legs (most often the one underneath him) vibrated rapidly. I once observed that a male had not inserted his hemipenis. Five seconds after "copulation" began, an amber-colored droplet appeared on each of the two terminal tips of the hemipenis. Three seconds later the male pulled his cloaca away from hers. As in all other sessions, the male released his bite-hold just after genital contact ended. Copulation took 11.1±3.2 (7-22) seconds. Immediately thereafter the male made fast (1-2 sec) semi-circles to figure 8's, over or under but especially in front of her, preceded by pushing his snout against the female. He stopped each circling movement on snout contact with the side of her head or body (Fig. 2), then rested his head on the female. These actions, which somewhat depended on her activity, decreased in frequency and velocity from a maximum of 10/min at the beginning to less than once in 4 min near the end. They lasted for 28±12 (15-68) min. In between these motions the male adopted an attentive posture close to the female, sometimes even on top of her, or on the rock under which she hid for a moment: His head and body were extremely raised with his very fingertips touching the substrate. At the same time he made quick lateral scanning movements with his head.

In view of the very open habitat of the species (Peters 1962, op. cit.), a functional explanation of this behavior is that the male is on the look-out for competitors: In this phase activities of other species in neighbouring cages caused fast dashes in their direction. If the female walked off, he either followed or prevented her from moving by increased circling thereby effectively barring her way. These behaviors preventing her "escape" are unique among the mating strategies of 24 (of the around 60 known) species of *Lacerta* and *Podarcis* observed by me. If more than one female was present, the male seemed unable to discern the recently mated one, and he divided his attentions, often even focusing on the wrong female, possibly since she tends to be more active than a recently courted one.

Sexual receptivity in the female lasts from one to six days after oviposition (one observation on day 11). On other occasions females reject the male with bites and tail vibrations.

Females laid 1-3 clutches of 4-5 eggs in March, April and May. A young female produced a first clutch of only two eggs in her first mating season.

At oviposition eggs measured 7.1±0.4 (6.0-7.9) x 12.0±1.0 (10.0-13.7) mm with masses of 0.39±0.05 (0.35-0.49) g (n=22). Eighteen eggs developed. Just before hatching they reached 11.4±0.9 (10.0-12.9) x 18.8±1.5 (16.2-20.8) mm and 1.37±0.22 (1.16-1.71) g. Incubation took 49±3 (45-52, n=14) days at 25° C, and 32 days (32-34, n=4) at 30° C. SVL of hatchlings (n=18) was 25.7±1.7 (23-28) mm, CL 42.7±3.5 (38-48) mm; mass = 0.51±0.03 (0.48-0.56) g.

After completion of the studies the animals will be deposited in the Rijksmuseum van Natuurlijke Historie (RMNH), Leiden.

SERPENTES

TANTILLA RUBRA RUBRA (Red Blackhead Snake). **ARBOREALITY.** The genus *Tantilla* is considered a nocturnal, fossorial form that lives under rocks, surface litter or in underground retreats feeding on arthropods, annelids, slugs, spiders and insect larvae. On 16 August 1978, a specimen (EAL 4566) was observed climbing a rough barked tree in a cleared, open area at 0930 h. It was clear and sunny. When first observed the snake was thought to be a vine or root until it was realized that it was moving upwards. It was ca. 3 m above the ground and out of reach when observed. It had to be flicked off with a collecting rake to make the capture. It was collected 9.8 km SW Cerralvo and 16.7 km W on Rancho El Milagro, Picachos Mts., elev. 457 m, Nuevo Leon, Mexico by Ernest A. Liner, Richard M. Johnson and Allan H. Chaney.

Submitted by **ERNEST A. LINER,** 310 Malibou Boulevard, Houma, LA 70364-2598 and **ALLAN H. CHANEY,** 1600 W Johnston 29, Kingsville, TX 78363, USA

XENOCHROPHIS FLAVIPUNCTATA (Common Keelback). **REPRODUCTION.** On 4 February 1989 a freshly laid clutch of 25 eggs was found in a community cage of this species at a local animal dealer's shop in Bangkok. The clutch was taken home and placed on a substrate of moistened vermiculite in an enclosed plastic jar. Incubation was achieved by leaving the clutch exposed to daily atmospheric temperatures. In Bangkok during February the mean maximum temperature is 32.7° C and the mean minimum 22.8° C. The mean maximum temperature in March is 33.8° C and the mean minimum is 24.6° C.

On 19 March 1989 neonates began emerging from the eggs and by the morning of March 20 the last had left the egg. Distractions prevented measurement until the sixth day after hatching. One hundred percent of the eggs hatched, but three of the hatchlings escaped. Of the 22 measured on 25 March 1989 the largest had a SVL of 141 mm., the smallest 110 mm. The $\bar{X}$ SVL was 121.55 mm. Hatchlings first began shedding the fourth day after hatching and the last of them had

completed their first shed six days after leaving the egg.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records have a **standard format,** and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles,** Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use metric for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged). Photographs may substitute for a preserved specimen only when the live specimen could not be collected (*e.g.,* it was a protected species or it was found in a protected area). Photographs must be deposited in a university or museum collection, and the catalog number(s) provided.

Please submit new geographic distribution records, in the standard format only, to Joseph T. Collins, Museum of Natural History, The University of Kansas, Lawrence, KS 66045, USA. Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata.* SSAR Herp. Review 10(1):1.

(NCN) = no recognized common name.

THE HEAT IS ON!

with VALENTINE'S OWN 14 WATT HEAT PAD (c95L pad 39 watts)

THOUSANDS ARE IN USE IN ZOOS AND HERPETOLOGICAL FACILITIES NATIONWIDE!

here's why:

HEAT PAD

UNIQUE CONSTRUCTION

HEAT PAD IS PORCELAIN, NOT METAL, FOR A "SOFTER" MORE EVENLY DISTRIBUTED HEAT AREA. 8 FT HEAVY DUTY CORD. MOISTURE PROOF, SMOOTH SURFACE FOR EASY CLEANING.

FUNCTIONAL SIZING

AVAILABLE IN 8" x 9" or 9½" x 22" SIZES . . . PERFECT FOR ANY APPLICATION. ONLY ⅜" HIGH AND EASILY CONCEALED.

SUPER VERSATILITY

COVER WITH ARTIFICIAL TURF OR SOD FOR NATURAL PLANTLIKE ENVIRONMENT. COVER WITH CERAMIC TILE, GRAVEL, ROCK, SAND, BEDDING OR DISPOSABLE LINER TO PROVIDE ROCKY SETTING. PERFECT SOURCE OF "BELLY HEAT" TO PROPERLY DIGEST FOOD.

AFFORDABLE

C-95 8" x 9" heat pad $18.00
C-95L 9" x 22" $40.00

FOB Hinsdale

RANA CATESBEIANA (Bullfrog). USA: WISCONSIN: Brown Co: Barkhausen Waterfowl Preserve, along western shore of Green Bay, Suamico (T25N, R20E, Sec 34/36). 1987. M. McFarland. Verified by P.A. Cochran. Photographic slide on file at University of Wisconsin-Green Bay Richter collection (1488s). First published county record (Cochran et al. 1987. SSAR Herp. Rev. 18:21,23), although acoustic records (calling males) were reported previously (Mossman and Hine. 1984. The Wisconsin frog and toad survey: establishing a long term monitoring program. Wisconsin Dept. of Nat. Res., Bureau of Endangered Resources. 13 pp.).

Submitted by **MIKE McFARLAND,** Barkhausen Water Fowl Preserve, 2024 Lakeview Drive, Suamico, WI 54173, and **RIANA BISHOP,** Division of Natural Sciences, St. Norbert College, De Pere, WI 54115, USA ●

SAURIA

ANOLIS (CTENONOTUS) DISTICHUS (Bark Anole). BAHAMAS: GRAND BAHAMA ISLAND: 24.1 km east of Freeport. 10 October 1988. H.A. Dundee. Verified by A. Schwartz. Subspecies not determined but Schwartz suggests a Bahamian subspecies (except *ocior* or *biminiensis*), most likely *dapsilis.* Tulane University (TU 21140). New island record. Dr. P. Fluck (pers. comm.) says this species (along with *Anolis* [*Norops*] *sagrei*) was on Grand Bahama as early as 1968. The species is locally common.

Submitted by **HAROLD A. DUNDEE,** Department of Biology, Tulane University, New Orleans, LA 70118, USA ●

ANOLIS SAGREI (Brown Anole). USA: FLORIDA: Brevard Co: Mobile home park along Hwy A1A, Melbourne Beach. 7 January 1988. P.A. Cochran. Verified by P.A. Cochran. Milwaukee Public Museum (MPM 23363). New county record (Godley et al. 1981. SSAR Herp. Rev. 12:84-86; Ashton and Ashton. 1985. Handbook of Reptiles and Amphibians of Florida. Part two. Lizards, Turtles and Crocodilians, Windward Publ. Co., Miami). The presence of more than one size class and the discovery of egg shell fragments among tufts of fiberglass insulation on the underside of a mobile home indicate that a reproducing population has been established.

Submitted by **P.A. COCHRAN,** Division of Natural Sciences, St. Norbert College, De Pere, WI 54115, USA ●

ANOLIS SAGREI SAGREI (Brown Anole). USA: LOUISIANA: Orleans Par: New Orleans, vic. Japonica St. and Claiborne Ave. 28 Oct. 1988. Stephanie Stevens. Verified by Robert A. Thomas. Louisiana State University Museum of Natural Sciences (LSUMZ 47957). Jefferson Par: Metairie, corner Airline Hwy (US 61) and N. Wilson St., Exotic Gardens Nursery. 5 Nov. 1988. R.A. Thomas and Patrick J. Thomas. Verified by R.A. Thomas and Douglas A. Rossman. (LSUMZ 47958-67). New state record. The latter is obviously an introduction at the nursery, presumably via plants imported from wholesalers in Florida. Population level is exceedingly high with all age classes present and has survived and prospered through at least two winters. Brown anoles are now seen in adjacent neighborhoods. The former (18.3 km east of the latter location) is presumed to have arrived on a plant purchased at the nursery (no additional specimens have been seen). Nearest known localities are Harris Co., TX (547 km west, Dixon 1987. Amphibians and reptiles of Texas. Texas A&M Univ. Press, College Station) and Marion Co., FL (785 km east, Ashton and Ashton 1985. Handbook of Reptiles and Amphibians of Florida. Part two. Lizards, Turtles, and Crocodilians. Windward Publ., Miami).

CNEMIDOPHORUS SEXLINEATUS SEXLINEATUS. (Six-lined Racerunner). USA: ILLINOIS: Williamson Co., 3.5 km E Crab Orchard (T9S, R4E, S13). 15 June 1982. W.T. McDowell and S.L. Turner. Verified by R.A. Brandon. Southern Illinois University at Carbondale (SIUC R-2107-2109). New county record. (Smith. 1961. The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Surv. Bull. 28:1-298).

Submitted by **WILLIAM T. MCDOWELL,** Biological Sciences Program, Southern Illinois University, Carbondale, IL 62901, USA ●

COLEONYX VARIEGATUS PENINSULARIS (San Lucan Banded Gecko). MEXICO: BAJA CALIFORNIA SUR: Isla Santa Margarita. 17 October 1983 and 29 April 1984. Francisco Reynoso. Verified by L. Lee Grismer. Universidad Autonoma de Baja California Sur (UABCS 0640, 1053-54). New insular record (Dixon 1970. Cat. Amer. Amph. Rept. 96.1-96.4).

Submitted by **FRANCISCO REYNOSO,** Museum de Zoologia, Universidad Autonoma de Baja California Sur. Box 21, La Paz, BCS, 23000, Mexico ●

GEHYRA MUTILATA (Stump-toed Gecko). MEXICO: BAJA CALIFORNIA SUR: La Paz. 20 September 1983. Clara M. Jimenez. Verified by L. Lee Grismer. Universidad Autonoma de Baja California Sur (UABCS 2885). First record of this species in Baja California (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians, Houghton Mifflin Co., Boston, MA).

Submitted by **FRANCISCO REYNOSO,** Museom de Zoologia, Universidad Autonoma de Baja California Sur. Box 21, La Paz, BCS, 23000, Mexico ●

HEMIDACTYLUS FRENATUS (House Gecko). MEXICO: BAJA CALIFORNIA SUR: La Paz. Verified by John W. Wright. Universidad Autonoma de Baja California Sur (UABCS 0331). First record of this species in Baja California (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians, Houghton Mifflin Co., Boston, MA).

Submitted by **FRANCISCO REYNOSO,** Museom de Zoologia, Universidad Autonoma de Baja California Sur. Box 21, La Paz, BCS, 23000, Mexico ●

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: ARKANSAS: Sebastian County: south side of Science building on the campus of Westark Community College, Grand at Waldron, Fort Smith, Arkansas. 8 June 1987. J.J. Wages. Verified by T.M. Buchanan and M.A. Paulissen. University of Arkansas, Department of Zoology (UADZ 3550). A breeding population has existed on the Westark campus for at least 17 years (T.M. Buchanan, pers. obs.) and geckos can be found on all buildings on campus except the library (which was built in 1987 and may not have been "colonized"). First record for Arkansas (Dowling 1957. Occ. Pap. Univ. Ark. Mus. 3:1-51; Heidt, et al. 1979. Checklist of reptiles of Arkansas. Ark. Acad. Sci. Biota Surv. Checklist no. 20, 3pp.).

Submitted by **MARK A. PAULISSEN** and **THOMAS M. BUCHANAN,** Division of Science, Mathematics and Engineering, Westark Community College, P.O. Box 3649, Ft. Smith, AR 72913, USA ●

JAPALURA KUMAONENSIS (NCN). Pakistan: NWFP, Manshera District, Shaheed Pani, in cleared, grassy, open areas in otherwise coniferous forest, near the local snowline (2300-3000 m elev.). 8 May 1988. Khalid J. Baig. Verified by W. Auffenberg. Florida Museum of Natural History, University of Florida (UF 72787). Additional specimens in the Pakistan Museum of Natural History, Islamabad. These represent the first records of this genus and species from Pakistan. The only earlier record with definite locality data is mentioned in Smith (1935. Fauna of British India, Vol. 2, Sauria. Taylor and Francis, London, 440 pp), who listed it from Almora, Naini-Tal, Kumaon District, Uttar Pradesh Province, India. This range extension is expected since the Himalaya ranges are continuous between the two definitely known localities.

Submitted by **KHALID J. BAIG,** Pakistan Museum of Natural History, Markaz F-7, Block 2, Islamabad, PAKISTAN ●

SCELOPORUS TORQUATUS MIKEPRESTONI. (NCN). MEXICO: NUEVO LEON: 19.6 km NE San Antonio de Pena Nevada, Puerto de Pena Nevada, 2743 m elev. 16 July 1980. Ernest A. Liner and Richard M. Johnson. E.A. Liner private collection (EAL 4751); 24.3 km NW San Antonio de Pena Nevada on La Joya road, Puerto de Pena Nevada area, 3002 m. 14 July 1980. E.A. Liner and R. M. Johnson. (EAL 4755, 2 specimens); 19.6 km NE San Antonio de Pena Nevada, Puerto de Pena Nevada, 2743 m. 6 August 1980. E.A. Liner. (EAL 4771); 18.3 km SW Zaragoza at La Encantada,

2743 m. 6 August 1980. E.A. Liner. (EAL 4780, 6 specimens); 18.5 km NE San Antonio de Pena Nevada at Puerto de Pena Nevada, 2743 m. 23 July 1983. E.A. Liner and Allan H. Chaney. TESTUDINES

CHELONOIDIS CHILENSIS (Chaco Tortoise). ARGENTINA: FORMOSA: Patiño Department: Estancia Sawicki, Los Immigrantes, Ruta Nacional No. 81 (km 1386), 8 km W of Ibarreta (25° 13' S, 59° 51' W). 7 March 1988. P. Fidalgo and G. Scrocchi. Verified by E. Richard. Herpetological Collection, Fundación Miguel Lillo (FML, Chelonii 031: Adult, skeleton). First record for the Department. The species was previously recorded from Formosa Departments of Pirané and Ramón Lista (Waller, T. 1986. FVSA—Amp. y Rept. (Cons.) 1(2):36-48).

Submitted by **ENRIQUE RICHARD,** Instituto de Herpetologia, Fundación Miguel Lillo, Miguel Lillo 251, 4000-Tucumán, República Argentina and Proyecto Herpetofauna (FVSA), Sección NOA, Rivadavia 105, 5 to "G", 4000 - Tucumán, República Argentina ●

CHELONOIDIS CHILENSIS (Chaco Tortoise). ARGENTINA: SANTIAGO DEL ESTERO: Pellegrini Department: Algarrobal Viejo (25° 43'S, 64° 02'W). 10 October 1988. E. Richard and J.M. Gómez. Verified by E. Richard. Herpetological Collection, Fundación Miguel Lillo (FML, Chelonii 030: adult male); Figueroa Department: Ruta Provincial no. 5, 32 km before Caspi Corral (between La Banda and Caspi Corral). 27 October 1985. M. Fabrezi, J. Langone, E. Lavilla, R. Montero and G. Scrocchi. Verified by E. Richard. (FML, Chelonii 008: adult male). First records for the departments. The species was previously recorded from Santiago del Estero departments of General Toboada, Jiménez, Quebracho, La Banda, Ojo de Auga, Río Hondo, and Alberdi (Waller, T. 1986. FVSA-Amp. y Rept. (Cons.), 1(2):36-48). The Pellegrini Dept. record is a contribution of the "Proyecto Tortugas" (Proyecto Herpetofauna -FVSA), supported by the Kantonaler Zürcher Tierschutzverein (Switzerland).

Submitted by **ENRIQUE RICHARD,** Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 - Tucumán, República Argentina, and Proyecto Herpetofauna (FVSA), Sección NOA, Rivadavia 105-5to "G", 4000 - Tucumán, República Argentina ●

CHELONIA MYDAS (Green Sea Turtle). ARGENTINA: CHUBUT PRIVINCE: Fondeadero Sarmiento shore (42° 15'S, 64° 04'W). 13 July 1988. G. Venegas. Verified by J.A. Scolaro. Centro Nacional Patagónico, Colección Herpetológica (CNP-H #0331). This is the most southerly record for the species on the Atlantic coast and the first to be recorded on Valdes Peninsula, near Puerto Madryn city (Frazier 1984. Las tortugas marinas en el Oceano Atlántico sur occidental. Asoc. Herpetol. Argentina. S. Divulg. 2. La Plata. 22 pp.). The specimen (carapace length 39.5 cm; mass 5.7 kg) was collected dying at shore.

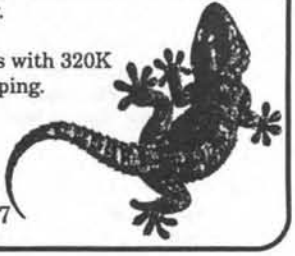
Computerize Your Field Notes

GECKO is very powerful, yet uses simple screen menus. It will allow you to:

Record genus, species, subspecies, number, locality, county, state, collector or observer, collection number and comments. Family, order and class are entered automatically.

Extract data for viewing, editing or printing by any combination of the above, e.g. iguanid lizard localities for Inyo Co., California or all herps seen in Texas from June through September.



List, edit or print data by order of entry, by date or phylogenetically in a variety of formats from simple species lists to complete records.

Copy selected records to files for use with data base programs, spreadsheets, or word processors.

Count the number of species for all or part of the data base, e.g. number of species for 1989 or number of species of *Hyla*.

GECKO incorporates a master species list of U.S. and Canadian herps. Lists of other vertebrates are available and can be merged for more comprehensive coverage. The master list can also be edited to accomodate taxonomic changes or new species. **Version 4.0** is now available. It offers the option to enter scientific names with simple, intuitive codes for fast, accurate data entry.

GECKO runs on IBM PCs and compatibles with 320K RAM and DOS 2.0 or later. $65 + $ 3 shipping. California residents add 6.25% tax.

CATALOGUE OF THE NEOTROPICAL SQUAMATA - PART 1 SNAKES, by James A. Peters and Roberto Donoso-Barros -- PART 2 LIZARDS AND AMPHISBAENIANS, by James A. Peters and Braulio Orejas-Miranda - Reprint with new material by P.E.Vanzolini (1986) The checklist of Central and South American snakes and lizards. The only work to cover the continent. Primary synonymies and keys in both English and Spanish. The update brings all the taxonomic nomenclature current through early 1986. 148 b&w illustrations, 672 pp., 8½ X 11" Softcover .$29.95

COR-059H
THE VENOMOUS REPTILES OF LATIN AMERICA, by Jonathan A. Campbell and William W. Lamar (1989) Provides the first comprehensive coverage of all the dangerously veneomous reptiles in Latin America. Detailed descriptions of 145 species of snakes and 2 species of lizard with discussions of their coloration, scutellation, distribution and habitat. 504 color photos, 62 line drawings, 115 maps, 6 color maps, Hardbound.. $ 59.50

STE-865H
KEEPING AND BREEDING SNAKES, By Chris Mattison (1988) The author brings together every aspect of snake husbandry necessary to keep and breed just about every species that the hobbyist is likely to encounter. Details everything from basic principles to environment, health, feeding, breeding and with individual chapters on he main genera. 184 pp. illus.with color and b/w photos. Hardcover $24.95

MPM-158s
SYSTEMATICS AND NATURAL HISTORY OF THE AMERICAN MILK SNAKE (Lampropeltis triangulum) 2nd Revised Edition - By Dr. Kenneth L. Williams (1989) Softcover 192 pages. Each of the 25 sub-species fully illustrated in color. Keys to identification, new maps, line drawings.$ 34.95

TFH-125h
KINGSNAKES AND MILKSNAKES, By Ronald G. Markel. All the species and subspecies of Lampropeltis are treated in detail and fully illustrated in color. Detailed information on the care and captive breeding of kingsnakes. Over 200 color photos, 144pp.,8½" X 11" Hardcover$29.95

COR-414H
TURTLES OF THE WORLD, by Carl Ernst and Roger Barbour (1989) The first modern reference book on turtles summarizing the classification and biology of all 257 species of turtles. The authors provide clear descriptions and keys for identification to family, genus and species as well as comments on range, ecology, reproductive biology, and other topics. The introductory chapter includes description and illustration of turtle anatomy and a discussion of turtle evolution. 50 color and 143 b&w illus., 5 tables, 21 line drawings, 290 pp., 8½" X 11" Hardcover $45.00

FOF-174H
CROCODILES AND ALLIGATORS, Edited by Charles A. Ross
A complete introduction to the 22 species of the world's crocodlians. Text written by over 25 experts with a full treatment of all species with three major sections: bio logy and evolution; natural history; and relations with humans. 250 photos and illustrations, most in full color 240 pages. 9½" X 12¼" Hard. $35.00

DAV-007H
CROCODILES, by Rodney Steele (1989) Covers the crocodilian family including the alligators, caimans and gavials, with species accounts and drawings of the heads from the top and side views. Chapter on conservation and farming. 19 color photos, detailed range maps Taxonomic coverage. 7½ X 9-3/4", 198 pages, HC $ 34.95

FOF-900H
LIZARDS OF THE WORLD, by Chris Mattison (1989) The latest of this series of books, now completing the herpetological group- (Frogs & Toads; Turtles & Tortoises; Snakes of the World- which are also available at $24.95 ea.) 62 color and 46 b.& w. photos, 17 figs., Environment,food and feeding, reproduction, Distribution, Captivity, 6 X 9" Hardcover. 192 pages . $ 24.95

RAN-824H
THE AUDUBON SOCIETY FIELD GUIDE TO NORTH AMERICAN REPTILES & AMPHIBIANS, BY JOHN BEHLER & F.WAYNE KING (1979-88) Descripption, Breeding, Habitat, Range - The Photographic Field Guide, with 657 full-color photographs. Easy to use, Easily carried in the field. Soft leatherette cover. 743 pages . . . . . $ 14.95

RCB-FRNZ
COLLIN'S HANDGUIDE TO THE FROGS AND REPTILES OF NEW ZEALAND, By Brian Gill (1986) This concise and fully color illustrated handbook describes the 43 species of frogs and reptiles found in New Zealand., 6 frogs, the tuatara, 9 geckos, 21 skinks, 2 sea-snakes and 4 marine turtles. 112 pages, Soft Vinyl cover. 4½ X 7½" $ 19.95

FOF-233H
BITES & STINGS: The World of Venomous Animals, by John Nichol (1989) An insight into the venomous animals (Toads, snakes, fish, spiders, frogs) and their relationship with man. Covers antivenoms, religion, myths, snake charmers, snake bite, keeping venomous animals, conservation etc. Well illus. with color and b & w photos. Appendix lists suppliers of antivenoms, their addresses and type of antivenom produced. 6 X 9" Hardcover, 208 pages . . . . . $ 19.95

SPECIAL CLEARANCE BIG DISCOUNTS

HO-286H
SNAKES "Struik Pocket Guides for Southern Africa" By Rod Patterson (1986) Illustrates in color 50 species of southern Africa's snakes. Habits, habitat and distribution. 64 pages, range maps, 4½ X 7" Boardcover $ 11.95
NOW REDUCED 20% FOR THIS SPECIAL SALE . .ONLY . $ 9.55

RCB-RESA
REPTILES OF SOUTHERN AFRICA, by Rod Patterson, Photography by Anthony Bannister (1987) A handsomely illustrated guide to 90 of Southern Africa's mo st fascinating reptile species. 238 excellent color photos compliment the text describing the various species. A chapter on snake bite covers prevention, first aid and treatment. There is a rather extensive illustrated chapter on keeping reptiles in captivity, breeding, diet and caging. 8½ X 11" Hardboard cover. 128pp.$39.50
NOW PRICE REDUCED 25% - NEW SALE PRICE - ONLY $ 29.50

RCB-SUSN
SURINAAMSE SLANGENINKLEUR "SURINAM SNAKES IN COLOR"
By Joep Moonen, W. Eriks & K. Van Deursen 119 Pages with 66 Color Photos. Softcover. Text in Dutch with brief English summary on each page.Excellent color photos showing 45 of the more common species of snake from this important South American country. English and scientific names are given. One of the few books on So.Amer.snakes. Reg. $29.95. SALE -20% OFF-ONLY $ 23.95

CLEMMYS GUTATTA (Spotted Turtle). USA: GEORGIA: Sumter Co: 6 km S. of Americus. 6 March 1989. Bob Herrington. Verified by Bob Herrington. Georgia Southwestern College Vertebrate Collection (#1651). New county record, extends the range 37 km NW in the Muckalee Creek drainage and substantiates the presence of a small population in this drainage (Camp and Powder. 1980. SSAR Herp. Review 11(3):80).

Submitted by **BOB HERRINGTON,** Department of Biology, Georgia Southwestern College, Americus, GA 31709, USA ●

CLEMMYS MARMORATA (Western Pond Turtle). USA: CALIFORNIA: Amador County: Sutter Creek, 5 km W Volcano. Sewage treatment pond, Amador City. Jackson Creek, 150 m N Hwy 88. 23 June 1987. Buskirk and Kinji Hayashi. Twelve turtles seen, 6 photographed, 1 captured. Calaveras County: North Fork Calaveras Creek above Highway 12, 3 km NW San Andreas. Pond, Jesus Maria Rd 10 km W Railroad Flat Rd. 4 June 1988. Buskirk. Seven turtles seen, 3 photographed, 1 captured. Eldorado County: Pond, Hwy 49 3 km N Pilot Hill. 16 June 1987. Buskirk and Hayashi. Four turtles seen, 2 photographed. Lassen County: Pit River at Pittville. 3 October 1988. Buskirk. Six turtles seen, 3 photographed. Nevada County: Pond, Hwy 49 0.5 km N Limekiln Rd. Pond, Auburn Rd 0.3 km N Hwy 49, 12 March 1988. Buskirk. Four turtles seen, three photographed. Placer County: Secret Ravine near China Garden Rd, 2 km E Rocklin. 16 June 1987. Buskirk and Hayashi. Four turtles seen, one photographed. Yuba County: Backwater of Dry Creek above Hwy 20. 12 March 1988. Buskirk. One turtle seen and photographed. All specimens verified by Harry Greene and documented by photographs deposited in Museum of Vertebrate Zoology. All represent new county records.

The records for Amador, Calaveras, Eldorado, Nevada, Placer, and Yuba Counties fill in some of the gaps in the known distribution of *Clemmys marmorata* in the Sierra Nevada foothills between Tuolumne County (MVZ 78788) and Butte County (Hayes and Cliff 1982. A checklist of the herpetofauna of Butte County, the Butte Sink and Sutter Buttes, California. Herp. Review 13(3):85-87). Two localities in Eldorado County with inadequate supporting information are listed in Appendix B of Brattstrom and Messer (1988. Current status of the southwestern pond turtle *Clemmys marmorata pallida,* in southern California. Final report for CA Dept. Fish and Game Contract C-2044. 47 pp.) The Lassen County record is the first for this turtle between Fall River Mills, Shasta County (Pope 1939. Turtles of the United States and Canada. Alfred A. Knopf. 343 pp.) and Ash Creek, Modoc County (Buskirk 1985. SSAR Herp. Review 14(4):116).

BOOK REVIEWS

Banglar Bonnyoprani. Vol. I. (In Bangla), by Mohammed Ali Reza Khan. 1987. Bangla Academy, Dhaka. 1-16, 1-169. 44 pl., 1 map. Price taka 125 (US $4).

Bangla or Bengali is spoken by an estimated 200 million people in Bangladesh and eastern India. Khan's volume is the first in a series of three that attempts to describe, in Bangla, the vertebrates (excluding fish) of the Republic of Bangladesh. The series is an expanded version of Khan's (1982) checklist: Volume I deals with the wildlife habitats and the herpetofauna, and volumes II and III (recently published) deal with the birds and mammals, respectively.

Dr. Mohammed Ali Reza Khan was until recently Associate Professor of Zoology at Dhaka University and is presently Curator of the Al Ain Zoo and Aquarium at Abu Dhabi, U.A.E. A member of the IUCN/SSC Commission on Education and of several of IUCN's Survival Specialist Groups, Khan is recognised as an authority on the wildlife of Bangladesh and is a prolific author.

The volume is divided into three chapters following an introduction: a definition of wildlife and a description of the various forest types of Bangladesh, a rather short account of the amphibians, and a longer one of the reptiles. The herpetofauna of this little country includes some 143 species (Khan 1982) and shows an admixture of both Indian- and Indo-Malayan elements. Geographic data of the country, considered to be the most densely populated by humans, are naturally of interest to wildlife biologists. According to Khan, Bangladesh has a total area of ca. 143,998 km², of which 8,300 km² consists of streams, rivers and estuaries and a mere 21,950 km² of various categories of forests. The last figure, Khan admits, is a government statistic, and the actual forested area is much less.

The chapter on amphibians is only 12 pages, a reflection of how little is known about this group. Earlier, Khan (1982) listed 19 species of amphibians that may occur in Bangladesh, but field work in some of the more inaccessible, frog-rich regions, such as the Chittagong Hill Tracts and Sylhet, should increase this tally. Most of the frog and toad species dealt with are widespread throughout the Indian subcontinent. Mention is made of the tree toad (*Nectophryne kempi*), which the author suspects is found in Sylhet district. The chapter closes with an account of the country's trade in frogs.

The last and longest (99 printed pages excluding illustrations) chapter concentrates on the reptiles. It commences, after a brief account on reptiles in general, with chelonians, a group well represented in Bangladesh (25 out of the 33 species found on the subcontinent). This is also a resource heavily exploited; between July 1989 and June 1982, the equivalent of Taka 30-40 million was earned by the country through turtle export. This legal trade, Khan writes, is a tiny proportion of the country's turtle trade, as very large numbers of these animals are smuggled across the border to India.

Of the 850 or so species of amphibians, reptiles, birds and mammals thought to occur

in Bangladesh, only two, according to the author, can be considered endemic. These are the black softshell turtle (*Trionyx nigricans*) which is known to be restricted to a tank attached to the shrine reportedly of Byazid Bostami at Chittagong and in nearby ponds, and the Indian eyed turtle (*Morenia petersi*), widespread in Bangladesh. Khan did suspect the occurrence of the latter within Indian limits, and the species has been found in recent years in the Indian state of Bihar (Das 1985; Moll and Vijaya 1986).

Each species account of chelonians consists of a brief description, with natural history and status notes, often of considerable interest. Khan deserves to be commended for the first records of numerous turtle and tortoise species from his country, including *Batagur baska, Kachuga tentoria, K. dhongoka, Melanochelys tricarinata, Cuora amboinensis, Indotestudo elongata* and *Manouria emys*. The section following the species accounts deals with various issues, including the turtle trade, the resultant decline in wild populations and ways to stem this.

Compared to the chelonians, the lizard fauna seems impoverished, with only some 17 species recorded (Khan 1982) and the present volume describes only the commoner or more interesting forms. One of these, the flying lizard, is reported from the country by the author, from the Chittagong forests, based on a sight record: Khan assumes this to be *Draco maculatus*. The locality of the present specimen, however, more closely approaches the distribution of *Draco blanfordii norvilli*, known from the nearby Indian state of Assam as well as northern Burma (see Musters 1983).

There are other interesting snippets of information on the lizard species. According to this book, the tokay gecko (*Gekko gecko*), the largest of the geckos, is used in folk medicine in Bangladesh as a substitute for the once available spiny-tailed lizard (*Uromastyx hardwickii*), which is found in Pakistan and north-western India. Khan restricts the water monitor (*Varanus salvator*) to the salt-water regions in the country. This species is widespread, though often very rare at present, in non-coastal regions in southeast Asia and in north-eastern India, and thus may be found (or was in the past) in Sylhet, Mymensingh and the three Chittagong Hill Tracts districts of Bangladesh. There is an example of this species in the Indian National Zoological Collection, maintained by the Zoological Survey of India (Reg. No. 2126) with data indicating that it was collected from Rangpore in northern Bangladesh.

Seventy-nine snake species are known to occur in Bangladesh (Khan 1988). The present volume describes, once again, the commoner or the more interesting forms, among which are the two python species, the rock python (*Python molurus*), now largely restricted to the Sunderbans, and the reticulated python (*P. reticulatus*), distributed over Sylhet and the Chittagong Hill Tracts. Of the Indian egg-eating snake (*Elachistodon westermanni*), the author has no information, apart from an old specimen, now at the British Museum, collected from Rangpore. Following the brief descriptions of snakes are (often too lengthy) accounts of the various superstitions associated with these reptiles.

All three crocodilian species of the subcontinent occur in this small country. The gharial (*Gavialis gangeticus*) is present only in the northern district of Rajshahi; the saltwater crocodile (*Crocodylus porosus*) in the Sunderbans; and the rarest, the once ubiquitous mugger or marsh crocodile (*C. pelustris*), restricted to a tank at Bagerhat. The status of all crocodilians is thus alarming and governments of nearby countries, such as India and Nepal could start 'croc diplomacy' by providing surplus animals from their rearing centres for a well-designed management programme for crocodiles in Bangladesh.

Creation of common names for the different species is the first step towards public education, and the author has been bold in this venture. He calls *Lepidochelys olivacea*, jalpaironger kachim; *Cuora amboinensis*, diba kachim; and *Elachistodon westermanni*, dimkhor shap, all literal translations of their respective English common names.

There are, however, numerous typos in the book, and names of two taxa have been misspelt throughout — *Cuora amboinensis* and *Varanus flavescens*. These mistakes have been repeated from the earlier checklist.

For illustrations, the volume relies heavily on Daniel (1983) from which line-drawings, black-and-white photographs, and color photographs and paintings have been borrowed. Quality of reproduction, however, is poor. There are several other problems with the illustrations: p. 50 (fig. 3.4) illustrates a low-shelled, keel-less emydid which cannot be *Kachuga tentoria* as its caption identifies it. Captions of *Eretmochelys imbricata* and *Dermochelys coriacea* have been interchanged on p. 66. On p. 70, the three monitor species found in Bangladesh are shown, but the caption provides no identification to the species.

A bibliography of 15 herpetological books and papers, 11 in English, 4 in Bangla, round out this interesting book. Published by the Bangla Academy, the book is not widely available. I had to make a trip to Dhaka to buy my copy.

Proceedings of a Workshop on Neotropical Distribution Patterns, by P.E. Vanzolini and W.R. Heyer, eds. 1988. Academia Brasileira de Ciencias: Rio de Janerio: 1-488.

This volume is based on a workshop held in January 1987 in Rio de Janeiro, Brazil, that brought together a diverse group of botanists, entomologists and vertebrate biologists to examine *pattern* in the distribution of Neotropical organisms. The volume is refreshing in avoiding the facile explanation of current distribution provided by reference to hypothetical Pleistocene refuges that change location and extent depending upon the groups analyzed and the imagination of the investigator. Not surprisingly in such a volume the approaches are diverse and depth of coverage uneven since the aim was to inform the participants of on-going research by others. Five of the papers in the proceedings are of particular interest to readers of *Herpetological Review* and illustrate and emphasize this uneven treatment. For herpetologists interested in South America this forms a useful update and corrective for some of the extreme refugial positions taken in the *South American Herpetofauna* volume edited by Duellman (1979).

John E. Cadle and J.L. Patton discuss the distribution of amphibians and reptiles (and mammals) along the eastern slope of the southern Peruvian Andes. Their treatment is very useful in detailing the altitudinal extent of species distributions for the region and the difference in pattern between mammals (greater diversity and finer vertical partitioning of the forested slopes) and herps. In addition they provide a cladistic basis for determining if the distributions of related taxa are the product of vicariant (allopatric) or gradient (parapatric) speciation models. They conclude that the former is the dominant one, without providing concrete analyses of relationships to support that conclusion. The interpretation of the origin of the fauna of the region is strictly dispersalist. Apparently the authors believe that the Andean slopes of southern Peru were a *tabla blanca* invaded from the north, south and east. Is it not possible that a substantial portion of the fauna is autochthonous and has been more or less evolving *in situ* from a time prior to any Andean uplift? This would certainly be in keeping with their conclusion that Pleistocene events are not the principal influence on differentiation of the fauna of this region.

In a second paper W.R. Heyer undertakes a detailed examination of the adequacy of the anuran data base as a basis for determining patterns and evaluating their significance east of the Andes. He concludes that even though the data base has dramatically increased in the last 10 years, it remains inadequate for reasoned discussion of pattern (too much missing data) or historical causes (too many possibilities for *ad hoc* hypothesis construction). Nevertheless, Heyer is willing to highlight certain features of Neotropical frog distribution, which based upon his broad knowledge and experience, provide a context for future study. These include an emphasis on the morphoclimatic domains of Ab'Sáber (1977) as correlates of distributions, the significance of open versus forest formations

and the tendency for forest species to have smaller areal ranges than those in other formations.

In another paper M.T. Rodrigues reviews the distribution of the lizard genus *Tropidurus* in Brazil with particular regard for broad ecological determinants. Although he emphasizes the importance of the morphoclimatic domains in this treatment, one is impressed by the fact that most of the figured species distributions show low fidelity in terms of restriction to a particular domain. More impressive is the essential absence of this genus from the Amazonian forest region while it occurs in all other open and forest formations. An interesting conclusion is that the caatinga area has an endemic component rather than simply being invaded by species from adjacent open formations during the drying trend of the current interglacial.

In a more general paper on lizard distribution P.E. Vanzolini provides an excellent and detailed review of species occurrence in Amazonian and Atlantic Forests and the principal open-formations (caatinga, cerrado and Chaco). Other major areas are covered in less detail. This minor flaw is far outweighed by the opportunity to have in one place a summary of the thoughts of the leading authority on South America's lizard biogeography. Vanzolini concludes that the basic patterns were established during Tertiary (Mio-Pliocene) and many species date from that period (others however are products of Quaternary climatic cycles), that wide-ranging taxa are the exception and that *in situ* speciation within major domains is the rule.

The final paper in the proceedings, *A New Look at the Iguania* by E. E. Williams, encompasses a much wider range than any of the others, forming an attempt to analyze the phylogeny, biogeography and evolutionary processes responsible for differentiation in a major clade of lizards. While this effort seems somewhat far afield from the central issues of the workshop, it is of considerable value to have this summary of Williams' ideas on these subjects. After all, he has been deeply immersed in the study of one of the largest components of this group (the anoles and their allies) for over 30 years. Because of the space limits for this review only a few of the most important features of the *New Look* are touched upon here. Williams' phylogenetic analysis is based upon 13 features (out of 49) utilized by Etheridge and de Queiroz (1988) and two additional scale features. He concludes that the Iguania are comprised of a Gondwanan clade (morunosaurs*Polychrus,* anoloids, oplurines and chameleons) and a Laurasian one (all other iguaninians, including agamids). He regards anoloids as being the sister group to chameleons and oplurines, which are in turn sister taxa. These proposed relations are based primarily on post-xiphisternal inscriptional rib conditions, sensory scale organ similarities and ulnar nerve position. These views are now placed in considerable doubt by the more recent rigorous, cladistic analysis (67 characters) of Frost and Etheridge (1989), who conclude that "agamids" and chameleons are sister taxa and not particularly closely allied to oplurines or anoles.

Williams found, as did Frost and Etheridge (1989) that numerous apparent homoplasies make resolution of relationships among the major subdivisions in the Iguania difficult. He argues that a rule of Geographic Contiguity may be "at least" as valuable as parsimony (or compatibility) in evaluating homoplasy, i.e. homoplasy may be rejected as an explanation of character incongruity when evidence suggests that the clades in question have been contiguous or sympatric at or near their time of origin. It is partially this rule that led Williams to propose the anoloid, oplurine and chameleon relationship. In light of the work of Frost and Etheridge (1989), this idea seems to have little merit in explaining character distributions in higher taxa. It also appears, in the example given by Williams, that his choice from among several possible homoplasies as to which are indicative of relationships is subjective. Nevertheless the concept that the geographic distribution of character states may be important to phylogenetic analysis needs to be explored on a wider basis.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to rteview herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations and photographs. Manuscripts submitted must be typed, double spaced, on 8.5X11 inch paper, and should be sent in duplicate. We encouregе submissions on Macintosh disks, though we can also work with TEXT (ASCII) files submitted on IBM and compatible floppies. **Herpetological Review** is composed on a Macintosh SE using Microsoft Word, which accepts files from several other word processor applications. Format your documents full-page width; we will fit to **HR** format. Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8X10 inches black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. Herpetological Review will accept commercial advertising. Rates and copy information are available from the advertising manager. Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats. Contact the Managing Editor for details. All ads are accepted at the Editor's discretion.

Society For The Study Of Amphibians And Reptiles

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (4 issues annually), **Herpetological Review** (4 issues annually), and occasional issues of **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1989

Student member.....$25.00*	Sustaining member.....$50.00*
Regular member.....$35.00*	Contributing member.....$75.00*
Institutional subscription.$60.00*	Life member..(see below)...$600.00*

***Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00.

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, draft on a US bank, or by Mastercard or Visa (include account number and expiration date of credit card). Life memberships may be paid in 3 consecutive payments

Subscriptions to Herpetological Review only are available for $12.00 annually.

Subscriptions outside of the US require a surcharge of $8.00 for air delivery if airmail is desired. Subscribers to HR only are not members of the Society.

Catalogue of American Amphibians and Reptiles: subscription $15 annually ($3.00 air delivery surcharge if airmail is desired.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc., RFD 6 Box 1, Lawrence, KS 66046. Steve Meseraull, Printer. POSTMASTER: Send form 3579 to the editor.

1990 JOINT ANNUAL MEETING

The 38th Annual Meeting of

THE HERPETOLOGISTS' LEAGUE

and The 33rd Annual Meeting of

THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

at

TULANE UNIVERSITY
New Orleans, Louisiana

5-9 August 1990

Meeting Site

Tulane University is a private, non-sectarian university composed of 11 schools and colleges enrolling approximately 11,000 students. The main campus is located in a residential area of New Orleans, a city with a metropolitan area population of over one million inhabitants. The city is located on the Mississippi River and is one of the nation's largest and busiest seaports. New Orleans was founded in 1718 and preserves much of its early history in the Vieux Carre or French Quarter, an enclave of old buildings built in the French style of the 1700's. Other parts of the city contain exquisite old mansions from the mid 1800's.

The warm, maritime climate supports lush vegetation, much of it imported from tropical and semitropical regions. The physical setting and many unusual provincial customs make New Orleans a haven for tourists. The city is a focal point for jazz music, and more recently the music of the Cajuns (early French settlers of southern Louisiana) has grown popular in night clubs. The cuisine is internationally famous and some of the world's great restaurants are located here. Featured foods are especially outstanding seafood, French, Creole, and Cajun. The surrounding countryside ranges from the great expanses of coastal salt marsh to large tracts of swamp forests and pine-hardwood forests.

The meetings will take place in the University Center Building and housing is available in the nearby dormitories, thus a very compact setting.

Technical Paper Presentations

Research reports will be given as oral presentations at several concurrent sessions, or as poster sessions. No definite symposium topic has been furnished as yet, but the Zoo Liaison group will likely have one. Deadline for paper titles and abstracts is 15 May.

Special Events

Monday night, 6 August: Social gathering

Tuesday evening, 7 August: A barbeque, and later that evening the Dennis-Juterbock-Adler slide shows and the Adler video presentation on the 1989 World Congress of Herpetology meeting.

Wednesday night, 8 August: The very popular auction conducted by Joseph T. Collins. Attendees are encouraged to donate books, art items, and other herpetological materials; proceeds are used to defray costs of the annual meeting and help support the two societies' activities. Receipts will be given for all items sold (they are tax deductible contributions). Contributed items for this event should be sent or brought to Dr. Harold A. Dundee, Department of Biology, Tulane University, New Orleans, LA 70118, USA

Live herpetofaunal exhibits

5-9 August: Commercial artist and exhibitor displays.

Accommodations and Meals

Accommodations in residential halls are available with or without linen service; singles in hall with community bath are $19.50/night without linen, $22 with linen; doubles in these halls are $12.50/night/person without linen, $15 with linen. In 4 bedroom apartments with two baths and kitchen facilities singles are $22/night without linen, $24.50 with linen. Family rates (two adults and up to three children) for a family apartment with kitchen $70/night/family without linen, $75 with linen.

The university accommodations *are not subject to the 11% tax* normally applied to regular hotel accommodations. Registrants occupying residential halls receive free campus parking privileges.

The University Center cafeteria will be open regularly for breakfast and lunch on a cash basis; arrangements hopefully will be made to have them open for Monday, Wednesday, and Thursday evening meals. An Arby's fast food outlet in the University Center is open throughout the day. Other food facilities are generally 1/4 to 1/2 mile distant.

Meeting Anouncement

A detailed program and call for papers will be mailed separately in late February. Additional information can be obtained from the meeting chairperson, Dr. Harold A. Dundee, Department of Biology, Tulane University, New Orleans, LA 70118, USA. (504) 865-5191. All interested persons are welcome to attend. Non-members should write to the meeting chairman for registration forms. ●

SSAR BUSINESS

1989 KENNEDY STUDENT AWARD

The Society is pleased to announce that the winner of the 1989 Kennedy Student Award, given for the best paper by a student published in Volume 22 of the Journal of Herpetology, is Leo J. Fleishman of the Department of Zoology, University of Texas at Austin (formerly of Cornell University and the Smithsonian Tropical Research Institute). Mr. (now Dr.) Fleishman's paper (The social behavior of *Anolis auratus*, a grass anole from Panama) appeared in **J. Herpetol.** 1988, pp. 13-23.

The Kennedy Student Award Committee consisted this year of J. Eric Juterbock (Chair), Robert E. Gatten, Jr., Ken R. Marion, John S. Mecham, and Laurie J. Vitt. ●

CONGRESS PHOTOS WANTED

The Society requests that members who attended the First World Congress of Herpetology and who took photographs of events, people, speakers, posters, or anything which occurred at and was related to the meeting, donate "seconds" or duplicates of the slides/prints to the SSAR archives. Please mail them to: J. Eric Juterbock, SSAR Secretary, Department of Zoology, Ohio State University, Lima, OH 45804, USA. ●

RECYCLED HERPETOLOGY

Back issues of scientific publications can be put to work elsewhere if they no longer fill your needs. Libraries in other countries suffer as much as our own from lack of funds and could benefit enormously from what you or your institution find of no further use.

If you are willing to pack up and ship, we can pass along the names and addresses of institutions which have approached SSAR for help. In most cases, all scientific publications are appreciated but herpetology is likely a special interest since the contact is through SSAR.

For further information on this program, contact Ruth M. Zantzinger, 2108 Cherry Street, Philadelphia, PA 19103-1312, USA. ●

ERRATUM

Readers of the **GEOGRAPHIC DISTRIBUTION** section please note the following error: In the September 1989 [20(3):75] issue of *HR*, under **Caudata,** a typographical error appeared in the first line of the account for the blue-spotted salamander hybrids. The correct name should have been ***"Ambystoma* (n) *laterale-jeffersonianum."*** The editor regrets the error and extends his apologies to the author of this note. ●

LETTERS TO THE EDITOR

EDITOR:

I read with interest Frost and Collins, 1988, nomenclatural notes (*HR* 19(4):73-74), but am not in complete agreement, especially with respect to kingsnake names I am obliged to use. Those authors correctly note that forms usually considered adjectival in context and orthography may instead be nouns in apposition, as Collins the Kansan or Eric the Red. Thus *Lampropeltis getulus* may be read as Shine-skin the Getulian, and *Lampropeltis g. niger* as Shine-skin the Black. Indeed, should *getulus* have been intended as an adjective, it might have been better coined as *getuliae, getulianae,* or *getulianensis.*

While I might agree with Frost and Collins that these orthographies are likely just mistakes, the situation is equivocal and, therefore, not compelling. To effect the name changes suggested requires, I believe, an unequivocal argument to be compelling.

I further note that the problem of *panamintus* does not arise as long as one keeps the species in genus *Gerrhonotus;* similarly, the problems of *silus, maculosus,* and *punctatus* are solved by leaving the species in *Crotaphytus.* No competent systematist could possibly believe the polytopic, polyphyletic, extreme of pattern variation named *"pallidula"* is a valid subspecies of the garter snake *Natrix sirtalis.*

JAMES D. LAZELL, JR.
6 Swinburne Street
Conanicut Island, RI 02835, USA ●

EDITOR:

In answer to Lazell's letter (bottom to top):
1. The comment by Lazell with regard to *pallidula* does not address a nomenclatural issue and is just a short polemic on the systematics of garter snakes. Collins and I addressed nomenclature, not systematics, in our paper and I question why Lazell addresses this issue in his letter.

Because Lazell did address systematics I will comment on his use of *Natrix* in place of *Thamnophis.* Unless Lazell's taxonomy is not intended to represent evolutionary relationships, this usage does not fit what is understood about the phylogenetic history of North American natricines. Because the Thamnophiini is a highly corroborated monophyletic group (Rossman and Eberle 1977, Herpetologica, 33:34-43; Lawson 1986, *In:* Rocek (ed.), Stud. Herpetol., Prague: 227-234), the taxonomic changes required to use *Natrix* for any New World species would be minimally that all of the nominal North American genera *Adelophis, Clonophis, Nerodia, Regina, Seminatrix, Storeria, Thamnophis,* and *Virginia,* as well as the African *Afronatrix,* and likely the Asian *Sinonatrix, Amphiesma, Rhabdophis,* and *Xenochrophis* (Lawson 1986), would necessarily be placed in *Natrix,* not just the species that are superficially similar to Old World *Natrix.*

Lazell's opinion notwithstanding, I am unaware of any data, other than general superficial similarity (the same measure that would evaluate an orange as more like a basketball than an apple), that could support the placement of *Thamnophis* in *Natrix.*

2. Lazell is welcome to retain *silus, maculosus,* and *punctatus* in *Crotaphytus,* but, like point 1, this is not the issue under discussion.

3. *Panamintinus* (like in points 1-2) also retains its form if placed in *Gerrhonotus.* Although this is irrelevant to our point, keeping *panamintinus* in *Gerrhonotus* would require synonymizing *Abronia, Mesaspis,* and *Barisia* (besides *Elgaria*) with *Gerrhonotus* (see Good 1989, Univ. California Publ. Zool., 121).

4. Contrary to Lazell's position on *getulus* or *niger* possibly being "the getulian" or "the black," the burden falls on Lazell to make the case for improper Latin to be compelling, and for proper Latin not to be compelling. Regardless of what Linnaeus should or could have do, the fact remains (see any Latin dictionary) that *getulus* in the combination *Lampropeltis getulus* is bizarre. As originally formed it was *Coluber getulus,* which under Lazell's reasoning could be "The Getulian [a noun] Snake" or "Getulian [adjective] Snake." Which do you think is reasonable? I find this question hard to categorize as "equivocal" (Lazell's term). Article 31(b)i (which is the rule whereby equivocal adjective or noun status is decided) does not come into play, because *getulus* and *niger* cannot reasonably be treated as nouns in combination with *Lampropeltis.* This isn't a case of *crucifer* or *rhombifer,* but only of adjectives that can be considered nouns under the most forced reasoning. Any other position is simply trying to justify usage *a posteriori.*

NEWSNOTES

1990 SWRS STUDENT RESEARCH GRANTS

The American Museum of Natural History will award several research grants ($200-$1,000) to graduate students or recent postdoctoral students in support of studies undertaken at the Southwestern Research Station in Portal, Arizona. The thirty-five year old research station is located at 5400 feet elevation in the Chiricahua Mountains of southeastern Arizona. Easy road access to five Life-zones, Lower Sonoran to Hudsonian, provides many unique opportunities for researching one of the most species-diverse biota in North America.

Applications (to be filed by 15 February 1990) are available from: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024, USA. ●

VOLUNTEER PROGRAM AT SWRS

Approximately 20 volunteer positions are open in 1990 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for four hours per day of routine chores, with the remaining time available for research activities.

The program is open to both undergraduates and graduate students; the latter may pursue their own research projects. *Faculty knowing of promising students should alert them to this opportunity* for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between 15 March and November. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March through May) should submit forms by 15 February, summer volunteers (June-August) by 1 April, and fall volunteers (September-November) may apply any time.

For application forms, write: Resident Director, Southwestern Research Station of the American Museum of Natural History, Portal, Arizona, 85632, USA (602) 558-2396. ●

RESEARCH OPPORTUNITIES IN FIELD BIOLOGY

The Edmund Niles Huyck Preserve and Biological Research Station announces the 1990 competition for support of field research in biology. Since 1938 the Preserve, located on the Helderberg Plateau in southwestern Albany Co., NY, has supported more than 250 scientists working on the ecology, behavior, and evolution of its flora and fauna. During 1989 the Preserve funded nine scientists from throughout the U.S.

The preserve consists of 2000 acres of hardwood-hemlock forest, pine and spruce plantations, old fields, clear-cut areas, lakes, streams and waterfalls. The physical facilities include residences for researchers, a modern research center with wet and dry laboratories, a library, workshop/barn, boats, and weather station.

Support of up to $3500/yr is available to those pursuing advanced degrees and those with the Ph.D. Applications for grants are due by 1 February 1990, and awards are announced by the end of March. For more information call (518) 797-3440 or write: Richard L. Wyman, Ph.D., Director and Biologist, E.N. Huyck Preserve and Biological Research Station, P.O. Box 188, Rensselaerville, New York 12147, USA. ●

INFORMATION REQUEST

A Regional Studbook for South American river turtles (genus *Podocnemis*) is being established. Individuals or organizations holding any species of this genus are invited to participate in the program by supplying information about their captive specimens, particularly as it relates to captive reproduction. Send information or inquiries to: Richard Sajdak, Milwaukee County Zoo, 10001 W. Bluemound Road, Milwaukee, WI 53226 or call (414) 771-3040. ●

NIXON GRIFFIS FUND AWARDS GRANTS

The Nixon Griffis Fund for Zoological Research (NGFZR), established in 1984 by New York Zoological Society Trustee Nixon Griffis, awarded nine research grants in May 1989. One of the grants was awarded in the field of herpetology. Martin S. Wilder and Barbara B. Bonner of the University of Massachusetts at Amherst received funding for their project "Studies on the bacteriology and phagocytic cells of the red-eared slider turtle, *Trachemys scripta*."

NGFZR grants are available to members of the zoo and aquarium community. Fund recipients may be keepers, curators, veterinarians, or research and consulting biologists. Grants, not to exceed $3000, are awarded semi-annually. Closing periods are 1 January and 1 July.

For further information, contact John Behler, Coordinator, Nixon Griffis Fund for Zoological Research, c/o New York Zoological Society, Bronx Zoo, Bronx, NY 10460, USA. ●

WORKSHOP ON MORPHOMETRICS IN SYSTEMATICS AND EVOLUTIONARY BIOLOGY

A workshop* will be conducted by F.J. Rohlf, F.L. Bookstein, L.F. Marcus and guest lecturers at the State University of New York at Stony Brook 10-23 June, 1990. Participating students must be familiar with statistics and microcomputers and show promise of incorporating morphometrics into their teaching or into an active research program. Students may be advanced graduate students, postdoctoral researchers, or professionals. Thirty students will participate, and 20 can receive participant costs (travel, lodging, meals, course materials). Application forms must be received by 15 February 1990 to be considered. For additional information and an application form, contact M.A. Bell, Coorganizer, Department of Ecology and Evolution, State University of New York at Stony Brook, Stony Brook, New York 11794-5245. (516) 632-8574. Fax (516) 632-8577 / BITNET - MABELL@SBBIOVM. (*Contingent upon availability of funds.) ●

MEETINGS

SPNHC 5TH ANNUAL MEETING

The Society for the Preservation of Natural History Collections will hold its fifth annual meeting 7-11 May 1990, in Chicago, hosted by the Field Museum of Natural History. The tentative program includes sessions on pest control, museum hazards and safety, problem solving, and a symposium on conservation of exhibit specimens. The meeting is open to anyone with a professional interest in the management and preservation of natural history collections. For further information, please contact David Willard, Bird Division, Field Museum of Natural History, Roosevelt Rd. at Lake Shore Dr., Chicago, IL 60605, USA (312) 922-9410, ext. 269. ●

CALL FOR PAPERS

The 14th International Herpetological Symposium on Captive Propagation and Husbandry will be held 20-23 June 1990, in Dallas-Ft. Worth, Texas. Individuals wishing to present papers dealing with the breeding and husbandry of reptiles and amphibians are invited to write or phone for a copy of guidelines for abstracts and papers. Please contact Thomas A. Huff, Reptile Breeding Foundation, PO Box 1450, Picton, Ontario KOK 2T0, Canada. (613) 476-3351 (day) or (613) 476-3691 (evening). Abstracts and titles must be submitted by 28 February 1990. ●

REGIONAL SOCIETIES

HERPETOLOGICAL SOCIETIES UPDATE

The June 1989 issue of *HR* contained a listing of all known active herpetological societies throughout the world. At this time, we report several additions or corrections to that listing.

FEATURES

CLUTCH SIZE AND FEMALE LENGTH IN *Opheodrys vernalis*

Clutch size was recorded for 49 gravid females incident to a study (Grobman 1941) of geographic variation in *Opheodrys vernalis*. Larger females contain more eggs than smaller females. The relationship (Fig. 1) is Y = .04X - 6.15 where Y is the number of eggs and X is the length of the female. Ford and Killebrew (1983) have demonstrated a similar relationship, Y = 0.64X - 13.0, for the number of young and the female snout-vent length for *Thamnophis butleri*. Seigel, Fitch and Ford (1986) and Ford and Seigel (1989) have provided information on additional species of snakes.

Another statistical relationship suggested by the data is that between clutch size and the two subspecies of *O. vernalis*. The mean number of eggs in nine *O. v. blanchardi* clutches is 7.3 and the mean number in 40 *O. v. vernalis* clutches is 5.7, the difference being statistically significant (t-test; P = < .02; Fig. 1). The apparent association between clutch size and subspecies may reflect the greater length of *O. v. blanchardi* as compared with *O. v. vernalis*.

An additional suggested derivative association is clutch size with latitude in the eastern subspecies. The mean number of eggs in six New Brunswick (Canada) clutches is 3.8; in nine clutches from Massachusetts and Maine, 5.2; and in five clutches from Ohio and Pennsylvania, 7.0. It appears that the number of eggs in a clutch decreases with an increase in latitude, a probable reflection of the smaller size of northern specimens of *O. v. vernalis* compared with southern specimens of that subspecies.

Blanchard (1933) gives the frequency of eggs in clutches from 62 specimens of *O. v. vernalis* and I am able to provide information from 40 additional clutches. The combined data for the number of eggs in the 102 clutches of *O. v. vernalis* may be described as $\bar{X} = 5.75 \pm 0.19$.

I am grateful to Samuel S. Sweet, University of California, Santa Barbara, and Scott M. Moody, Ohio University, Athens, Ohio, for their helpful comments on the manuscript.

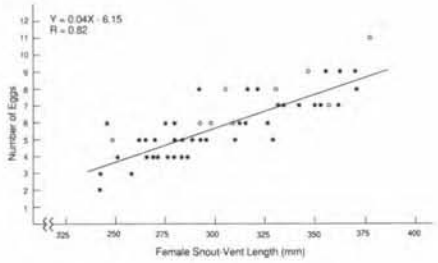

Figure 1. The relationship between clutch size and snout-vent length of 49 *Opheodrys vernalis*. Open symbols denote *O. v. blanchardi* while closed symbols represent specimens of *O. v. vernalis*.

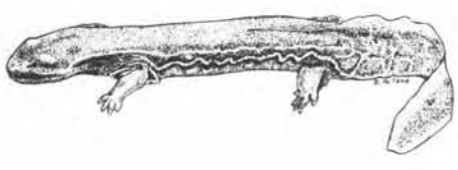
SALAMANDER OCCURRENCE WITHIN MT. ST. HELENS BLAST ZONE

The 18 May 1980 eruption of Mt. St. Helens released a blast of incandescent gas up to 200° C that traveled horizontally at a velocity estimated at 50 m/sec (Hammond 1980). Within a few minutes, the blast devastated an area of 500 km², leveling trees and killing people within the impacted region. MacMahon (1982) reported the survival of *Ambystoma macrodactylum, A. gracile, Dicamptodon ensatus* and *Taricha* sp. in the impacted region in 1981.

On 21 August and 5 September of 1982, we located 3 amphibian species (Table 1) 2.8 km inside the impacted region (elev. ca. 1100 m, T9N, R6E, Section 5, Skamania Co., Washington). The zone is characterized by fallen trees stripped of bark, branches, foliage, and embedded with pumice and lithic fragments, and the entire area is covered with grey ash 20-30 cm deep. The stream is 1-2 m wide, 5-10 cm deep, and is a tributary of Bean Creek. Flora adjacent to the stream included *Epilobium angustifolium* and Liliaceae and Compositae species.

All salamanders were located under bark within 1 m of the stream. From 1300-1630 hr, when the animals were found, air temperature was above 32° C in the sunlight and 20-25° C in the shade near the stream. Water temperature was ca. 10° C. Voucher specimens are deposited in the Herpetology Collection of the Department of Zoology, Washington State University.



The approximate age indicated by snout-vent length suggests that *Rhyacotriton olympicus* and *Plethodon vandykei* individuals are more than 2 years old and survived the blast. The likelihood that these salamanders migrated to this stream is low because: 1) Migration over or through the ash is difficult because ash sticks to moist surfaces, 2) The nearest area in which trees are still standing (but ashfall is heavy) is 2.8 km from where the salamanders were found, and 3) Bean Creek was heavily impacted along its entire length of ca. 5 km, making it highly unlikely that the salamanders migrated up the stream.

The newly transformed *Ambystoma gracile* may have left nearby St. Charles or Meta Lake. In the latter, we have found *A. gracile* eggs and larvae in 1982 and 1985, indicating that reproductive activity continues.

In late May of 1985, we examined the stream site to determine approximate conditions at the time of the year when the eruption occurred. The site, which is a v-shaped gulch ca. 10 m deep and 100 m long, was filled with snow ca. 3 m deep. If the site was similarly covered when the eruption occurred, the snow may have buffered the thermal and physical effects of the blast.

Table 1. Species, sex (F = femae, M = male, and J = juvenile,) and snout-vent length (SVL) of salamanders suspected of surviving the 18 May 1980 eruption of Mt. St. Helens.

SPECIES	SVL (mm)	SEX
Ambystoma gracile	40	F

COURTSHIP BEHAVIOR IN THE CHINESE BOX TURTLE, *Cuora trifasciata*

Despite the diversity of emydid turtles in Southeast Asia, and their frequent exploitation by humans, published accounts on the natural history of most species are rare. *Cuora trifasciata* is native to southern China and northern Indochina (Pritchard 1979). Although this species has been frequently imported into the United States for the pet trade, little appears to have been written regarding its habits either in the wild or under captive conditions. The limited observations offered here should ideally be supplemented by studies under natural conditions.

Two juvenile *C. trifasciata* of unknown origin were obtained in November 1981. Carapace lengths (CL) were 10.3 and 10.5 cm, and secondary sex characteristics were not apparent. Specimens were housed in a glass aquarium measuring 91x63x33 cm. Water depth was ca. 9.5 cm and a dry 60x33 cm platform illuminated by a 40 watt incandescent bulb was provided for basking. Room and water temperature varied from 20 to 27° C, with the coolest temperatures in the fall, due to the effects of central heating. The light was on about 12 h/day. Nearby windows provided some variation in photoperiod. The diet included minnows, earthworms, Purina Trout Chow®, and various fruits and leafy vegetables—all readily accepted.

By November 1983 the smaller specimen (CL = 13.1 cm) had developed a comparatively longer tail with the anal opening distal to the rear edge of the carapace, a male characteristic in many turtle species. The larger turtle (CL = 14.1 cm) retained a shorter tail with a short pre-anal length, and was presumed to be a female. One year later (1984) the two had carapace lengths of 14.5 and 15.2 cm respectively, and were separated due to aggressive behavior by the male, resulting in bites to the female's neck, feet, and shell. They were placed together every few days to observe any changes in interactive behavior.

OBSERVATIONS

In May 1985 the first display of what was considered to be true courtship behavior was observed. Upon being placed in the water in the female's tank, the male turned toward her, extended and lowered his head, and swayed it back and forth in a horizontal arc of about 30°. The female responded by also lowering her head and swaying it in a narrow arc. The male then swam backwards and increased the rate of head swaying. After this had continued for several minutes, the female turned away; no further courtship activity was observed and the male was removed after about an hour.

The following day the male was again placed in the female's tank. This time he immediately pursued and mounted the female, clasping the rear edge of her carapace with his hind claws. With neck extended downward he pressed his chin firmly on the female's withdrawn head; he appeared to increase downward pressure when she struggled and (presumably) tried to breathe (water was about 9 cm deep). After about 10 min the male bit and held the female's neck skin and attempted to drop backwards, possibly to bring his tail and cloaca into a copulatory position. However, her struggles finally dislodged him after about 5 minutes. The male was removed after several more minutes of pursuing and biting the female's shell and neck; the female suffered a significant wound on the neck skin.

The above behaviors, along with minor variations, were observed on numerous occasions. Normally the male would use horizontal head-swaying for several minutes before attempting to mount the female. The female would sometimes respond with similar swaying, but her usual response was to escape, often by leaving the water and crawling up the basking ramp. No actual copulation by this pair was observed, although the male often mounted the female's carapace and attempted to keep her head withdrawn, as described above. A rare complement to this "nose pressing" behavior was a vertical "bobbing" of the male's head over the female's head.

If the male were left in the female's tank, intense courtship activity lasting perhaps an hour was usually followed by long periods of "peaceful coexistence." The male could be induced to resume courtship by pouring fresh, cool water into the tank, or by putting food in the tank, which caused the female to become active. Although courtship by the male was observed throughout the year, his interest seemed highest in the spring.

DISCUSSION

The violent nature of the observed courtship behavior was remarkable. The female's neck bears significant scarring from repeated "nuptial biting." However, until studies of the behavior of this turtle under natural conditions are available, there is no way to be sure that the above observations are indicative of "normal" courtship activity.

Observations on this pair of *Cuora trifasciata* ended in June 1988; at that time the male had a carapace length of 16.0 cm while the female's carapace measured 18.3 cm. It might be presumed that the male was sexually mature at the time of courtship initiation; maturity cannot be presumed for the female. No evidence of ovulation was apparent during the observation period, and the size or age of sexual maturity in this species is apparently unrecorded.

UNIQUE BEHAVIORS IN CAPTIVE ROCK HORNED LIZARDS, *Phrynosoma ditmarsi*

In August 1983, several live *Phrynosoma ditmarsi* were collected in the Sierra Baviacora, Sonora, Mexico, for study of their behavior and reproduction in captivity. Growth and reproductive data have been summarized elsewhere (Montanucci 1989); herein I present observations on diel activity as well as some unusual and unique behaviors pertaining to locomotion, aggressive interactions and sleeping sites not previously reported in this species or other *Phrynosoma*.

Most of my observations are based on eight adults (four of each sex), three subadults (two males, one female), and eleven juveniles (five males, six females) which were the descendants of an adult female and male procured in 1983. The adults were housed in plexiglass cages, 76 x 56 x 28 cm high; juveniles were kept in 20 gal. aquaria (approx. 76 x 32 x 31 cm high). The natural microhabitat was simulated on the basis of field data and information provided in Lowe and Howard (1975). The lizards were maintained under Vita-Lite and black light (F40BL-48, General Electric Co.), with a seasonally adjusted photoperiod (for Clemson, SC). Indoor reflector floodlamps, 75 W and 150W, were used as a heat source for the 20 gal. aquaria and plexiglass cages respectively. Adults were fed grasshoppers and *Tenebrio molitor* (larva, pupa, and adult stages). Juveniles were reared on termites, small ants, and small *Tenebrio* larvae. All food was dusted with a vitamin-mineral supplement (Reptivite by Zoo Med has been used since 1987). Lizards were over-wintered between 13° and 16° C, with occasional drops to 8° C.

Phrynosoma ditmarsi and its southern Mexican relatives, *P. braconnieri* and *P. taurus* are long-limbed horned lizards compared with the superficially similar *P. douglassii* (Montanucci 1987: Table 9). *P. ditmarsi* inhabits rocky areas in Madrean evergreen woodland (Lowe et al. 1971; Roth 1971; Lowe and Howard 1975), and its long limbs may be an adaptation for crawling over such terrain. When crawling on flat ground, *P. ditmarsi* typically maintains the abdomen well elevated, in contrast to *P. douglassii* which usually allows the posterior abdominal area to drag. The elevated stance of *P. ditmarsi* would appear to facilitate traversing an irregular rocky surface.

P. ditmarsi exhibited a unique mode of locomotion which I have not observed in other members of the genus (I have observed all species except *P. braconnieri*). While crawling slowly, *P. ditmarsi* frequently stopped its

limb movements in mid-stride. For example, as one forelimb was raised, it was stopped just above the substrate, then brought forward slightly and stopped again, brought forward a little more, and then brought down to the ground. These slow movements were thus characterized by slight hesitations and numerous pauses. During this "slow-walk," individuals could be seen with either a forefoot or a hindfoot momentarily stopped in mid-air. If there is any adaptive significance to this behavior, it is not apparent, although it may enhance crypsis in the natural habitat. In captivity, this odd locomotion was clearly associated with feeding activity and what might be generally categorized as "foraging" behavior. It was not associated with courtship or mating activity. When crawling at a normal pace or when running, the movements of *P. ditmarsi* were similar to those of other horned lizards.

Considerable aggressive behavior was observed among juvenile *P. ditmarsi* under crowded conditions (5 or more individuals in a 20 gal. tank). Individuals bit each other on the limbs, feet, and tail. Once the saliva-coated extremities dried, it was difficult to wash the saliva off with water, as it tended to clump rather than dissolve in water. In some cases serious injury occurred to the tail tip and digits during episodes of biting, and saliva-coated skin surfaces usually precluded normal ecdysis. The aggression among juveniles did not seem to be associated with feeding behavior as these conflicts occurred even when the lizards had been fed to satiation. More likely, the aggressive tendency in juveniles is a spacing mechanism since conflicts could be virtually eliminated by reducing the number of lizards per cage; in nature, the neonates probably quickly disperse following birth. I have not observed aggressive behavior in juvenile *P. douglassii*, even under crowded conditions. Also, no aggression was observed among adult *P. ditmarsi* that was not in some way related to feeding activity. Lynn (1965) speculated that aggressive behavior has been lost in horned lizards, but juvenile *P. ditmarsi* and adult *P. cornutum* (combat noted by Winton 1917; Whitford and Whitford 1973) are interesting exceptions under captive and natural conditions, respectively.

At night, *P. ditmarsi* entered rock shelters or secluded themselves among rocks and grass clumps in the cages. Sand burial was seldom observed, usually once or twice during the active season and during ecdysis (Montanucci 1989). Juveniles (young of the year) sought the same retreats as the subadults and adults, but in addition, they climbed grass clumps and slept elevated from the ground. Juveniles were observed climbing grass clumps within a few minutes after the lights were switched off by automatic timer. Aggression was not observed among juveniles as they ascended grass clumps to sleep. Among a litter of 10 young, as many as four at any one time were found sleeping at the top of a clump, and occasionally (four of 30 observations), two or three lizards were stacked one upon the other. Apparently, the lizards were limited by the number of grass clumps available in the cage. By marking juveniles, it was determined that all 10 juveniles slept at the top of a grass clump at least once during a three-month observation period. If such behavior occurs in nature, it may allow juveniles to avoid detection by small nocturnal snakes and other small predators such as scorpions and solpugids. Juvenile *P. ditmarsi* are relatively defenseless due to their small size and virtual absence of protective spines.

TYPE CATALOGS OF HERPETOLOGICAL COLLECTIONS: An Annotated List of Lists

by
Charles R. Crumly

This annotated list of type catalogs for herpetological collections should prove useful to anyone engaged in taxonomic and/or systematic studies that rely upon the examination of museum material. Annotations for each entry include information regarding the contents of the referenced lists such as what kinds of types are listed, whether or not lectotypes are designated, what type of locality information is provided, how the list is organized, and references to other publications that have listed large parts of the collections. Also included are two indices: one lists the institutions for which type lists have been published, and the other is a family index wherein collections with types of specific families are cross-referenced. 51 pages.

Prepublication price	*$4.00*
After March 30, 1990	*$5.00*

Orders may be sent to Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056 USA.

The diel activity of three captive adults and two juveniles were noted daily from July through October, 1985. The number of days (X lizards) for which activity occurred in the AM/PM respectively is as follows: July 5/43; August 7/23; September 13/32, and October 14/23. The data suggest that these lizards are more active during the afternoon hours than morning hours during these months. During the monsoon season in Sonora, which begins about mid-July (Walter et. al. 1975), overcast weather typically develops in the afternoon and provides suitable conditions for foraging (e.g. decreased temperature, increased humidity, increased insect activity; see Lowe and Howard 1975). During the preceding months, hot, dry conditions preclude or severely curtail afternoon foraging by these lizards.

It is surprising that my captive *Phrynosoma* displayed increased afternoon activity since the obvious natural cues were not available to them. An endogenous rhythm is one possible explanation, or the captive lizards could have been responding to changes in barometric pressure which accompany frequent summer afternoon storms in South Carolina. On some days the captive lizards did not emerge until after the lamps were switched off, despite the existence of a suitable thermal gradient in the cage. In fact, the lizards could be encouraged to leave their shelters by switching off the lights prematurely. This behavior suggests a crepuscular tendency in *P. ditmarsi,* as well as, perhaps, the habit of foraging during overcast conditions. Consistent with this idea is the presence of some crepuscular-nocturnal arthropods (e.g. scorpions, Vince Roth, pers. comm.) in the diet of this horned lizard. *Phrynosoma* species are generally active earlier, as well as later, in the day than most other sympatric lizards (Heath 1965; Norris 1949), and apparent nocturnal activity has been reported for some *Phrynosoma* (Harris 1958; Williams 1959; Mays and Nickerson 1968).

Conclusions drawn from the behavior of captive animals are often considered to lack validity when extended to natural populations. I hope, however, that the observations noted here will provide the impetus for field investigations of this interesting and little-known horned lizard.

ACKNOWLEDGMENTS

I thank Tom Mann, Wade C. Sherbrooke, and Vince Roth and his field party for assistance in procuring *Phrynosoma ditmarsi.* Live specimens were imported under Mexican permit no. 0404 to Steve Prchal of the Arizona-Sonora Desert Museum in Tucson. Howard E. Lawler kindly made arrangements for importation. Thanks are also extended to C.H. Lowe, University of Arizona, for help in planning the itinerary. I am indebted to Tom Mann for his tireless and conscientious care of the horned lizards during my periodic absences. James C. Munger and Wade C. Sherbrooke read an earlier version of the manuscript and offered helpful suggestions for its improvement. Finally, I am grateful to Sr. Mario Navarro, B., Baviacora, Sonora, for his logistical help and hospitality during our visit to Rancho la Palma.

OBSERVATIONS ON THE NESTING ECOLOGY OF GREEN SNAKES (*Opheodrys aestivus*)

Because snakes are highly secretive, periodically dormant, and generally intractable, the use of radiotelemetry can provide ecological information that could not be gained otherwise. For example, discoveries of the nests of snakes occur rarely and are found fortuitously when investigators search for specimens. However, with radiotelemetry it is possible to directly observe an individual snake's nesting behavior and choice of nest sites. I used radiotelemetry to study nesting movements, nesting behavior, and nest sites of arboreal green snakes, *Opheodrys aestivus* (Plummer 1990). Because accounts of individual animals engaged in rarely observed events may contribute to a better understanding of a species' ecology (Fitch 1987), I here provide anecdotes concerning a little known aspect of the ecology of snakes, especially the heretofore unreported habit of nesting in tree cavities.

Miniature radiotransmitters (Model SOPI-1038-LD, Wildlife Materials, Inc.) were implanted into nine large (>500 mm snout-vent-length, SVL) gravid *Opheodrys.* On 19 June 1988, the telemetered snakes were released at their capture sites in the shoreline vegetation (primarily alder, *Alnus rugosa*) of a small lake 2 km west of Denmark, White County, Arkansas. Each snake was relocated several times each day until nesting occurred and once each day thereafter. Occasionally, I observed individual snakes through binoculars for periods of up to two hours.

The nesting ecology of *O. aestivus* at the Denmark locality may be summarized as follows (Plummer 1990): Prior to ovipositing, activities of female *Opheodrys* are restricted to small activity ranges averaging 15 m in length within the vegetation of a narrow band of alder at the shoreline. As the time of oviposition nears, snakes descend from their arboreal habitats and move terrestrially away from the shoreline and their activity ranges. Snakes

nest in small chambers within the hollowed interiors of living oak and hickory trees averaging 56 m from their activity ranges. Snakes move back toward their activity ranges after nesting. Selected individual accounts follow.

Opheodrys no. 5 exibited the most extensive nesting movements. After being monitored for 21 days in a typical pattern of restricted prenesting movements at the shoreline, she moved 55 m on 11 July and ascended an oak tree apparently in response to a severe thunderstorm. She remained coiled on a branch in the tree until fair weather returned on 13 July. She then descended and moved 45 m to a hollow hickory tree, spending at least two hours crawling on and in and out of the tree, but not ovipositing. Subsequent investigation of the tree hollow revealed four *Opheodrys* eggshells from a previous year. All eggshells contained longitudinal slits like those made by the egg tooth at pipping and were judged to have successfully hatched. After moving another 55 m on 13-14 July, *Opheodrys* no. 5 entered a second hollow hickory tree (Fig. 1A) and oviposited. On 15 July, she began moving toward her original activity range, eventually establishing a pattern of restricted movements in the vicinity of her original activity range similar to those of the prenesting period. On 15 July, I opened her nesting tree and found three freshly opened *Opheodrys* eggs with contents removed, apparently by a skink, *Eumeces laticeps*, which had been brooding a clutch of 11 eggs in the same hollow.

Opheodrys no. 104 moved from her activity range to a nesting site 30 m distant on 26 June and oviposited the same day. She then moved back to her activity range on 27 June where she was monitored until 15 July. The hollow oak tree where she oviposited contained four *Opheodrys* eggshells from a previous year, all appearing to have successfully hatched.

Opheodrys no. 604 moved from her activity range on 24 June directly to a tree where she was observed trying unsuccessfully to enter a small opening (Fig. 1C). After she abandoned her efforts, I opened the cavity and found 16 *Opheodrys* eggshells from previous years. Based on appearance, the eggshells could be segregated into a younger group of five and an older group of 11 eggs, all appearing to have successfully hatched. Apparently, growth of the tree had decreased the diameter of the opening and prevented her entrance.

Prenesting and nesting behavior of other *Opheodrys* were similar to those above. Of special note is the persistence shown by no. 110 attempting to enter a tree on 6 July. She was observed for over an hour attempting entrance into the rotted interior of an oak tree (Fig. 1B), eventually abandoning her efforts and retreating to a small nearby bush where she coiled and became inactive. Three hours later, she continued her efforts and eventually gained entrance into the tree where she oviposited (Fig. 1D).

Although nesting in tree holes containing eggshells from previous years could result from communal nesting of several individuals, the behavior of no. 604 suggested that she returned to a site previously used. She moved 55 m directly away from the shoreline to a tree, climbed 3 m up the trunk to a small opening difficult to detect by two humans from the ground, and for 30 minutes attempted to enter a cavity containing old eggshells. Along her path she passed within 5 m of 52 trees, 22 of which were hollow (Plummer 1990).

At least five authors have reported finding eggs of *O. aestivus* under surface cover (summarized in Plummer 1990), observations which question the prevalence of tree cavity nesting by this species. The discovery of an *O. aestivus* nest containing seven fresh eggs 10 July 1989 in a tree cavity on the Savannah River Site near Aiken, SC (M. Gibbons and T. Mills, unpublished data) suggests that the behavior is geographically widespread. Also suggestive of tree cavity nesting is the record of a large communal *O. aestivus* nest found in the insulation of a metal refrigeration panel which was standing upright against an oak tree in North Carolina (Palmer and Braswell 1976). The greater number of references to nesting under surface cover probably reflects more where field workers search than an actual nesting affinity of *Opheodrys*. Because nests in tree cavities are difficult to detect without adversely affecting the trees and since routine field use of chain saws is neither desirable nor recommended, this bias will not likely change. Despite these difficulties, I encourage field workers to nondestructively investigate tree cavities when possible (McComb and Noble 1981).

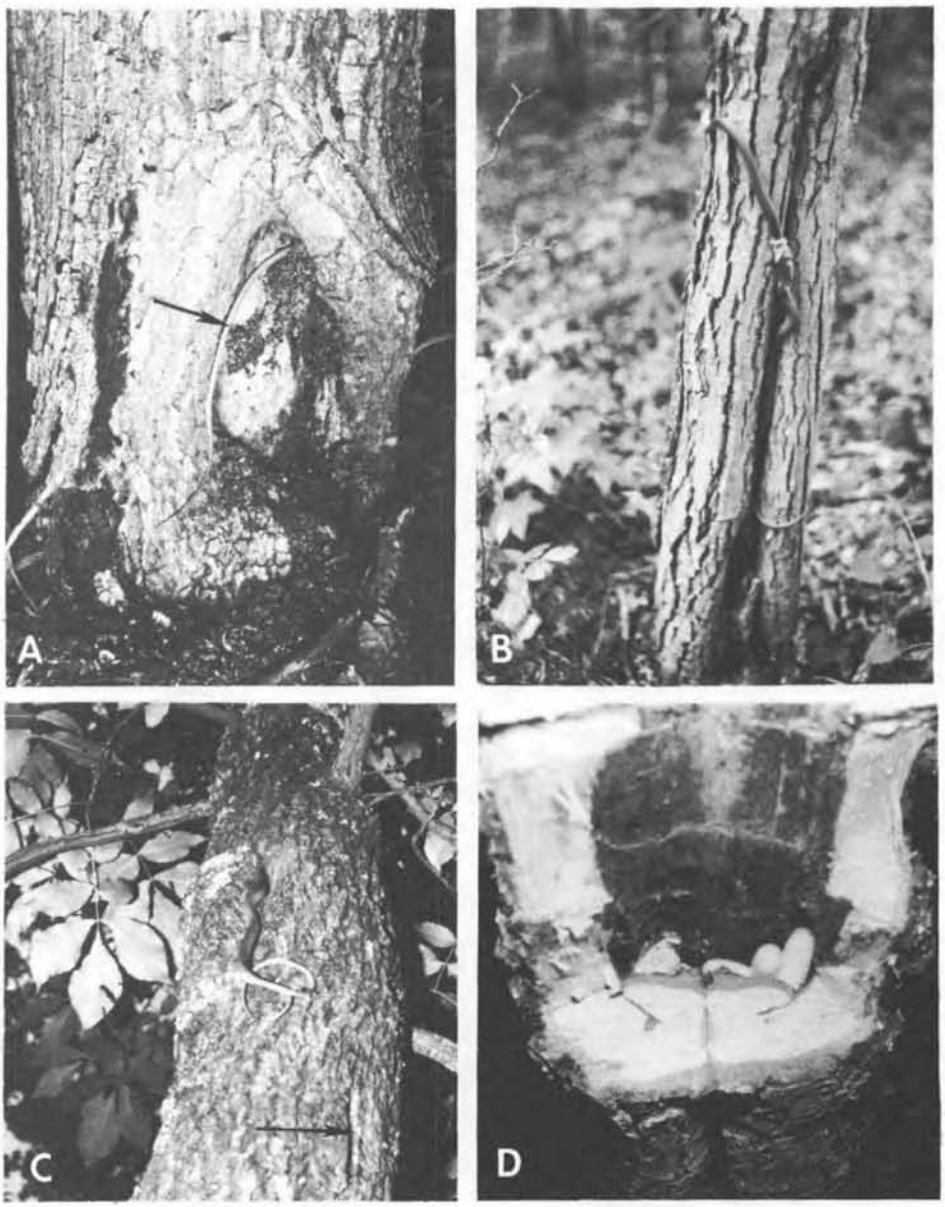

Figure 1. Nesting ecology of *Opheodrys aestivus*. (A) *Opheodrys* no. 5 entering nest tree at ground level (arrow). (B) *Opheodrys* no. 110 investigating tree where she later nested (see 1D). (C) *Opheodrys* no. 604 attempting to enter nest tree 3 m above ground level. Note slit where new tree growth has closed an old opening into the tree hollow (arrow). Sixteen *Opheodrys* eggshells from previous years were found within this tree. (D) Nest cavity and eggs of *Opheodrys* no. 110 exposed by opening tree with a chain saw.

ACKNOWLEDGMENTS

I thank C. Ransom for permitting me the use of his property to study *Opheodrys,* B. Forsythe for assistance in the field, and J. Congdon and W. Gibbons for comments on the manuscript. This study was supported in part by a Faculty Research Grant from Harding University. Manuscript preparation was supported by contract DE-AC09-76SROO-819 between the Department of Energy and the University of Georgia's Savannah River Ecology Laboratory.

TECHNIQUES

A NEW THERAPY FOR MARINE TURTLES PARASITIZED BY THE PISCICOLID LEECH, *Ozobranchus branchiatus*

Marine leeches, *Ozobranchus* spp., are prominent ectoparasites on the green turtle, *Chelonia mydas,* in the Hawaiian Islands and on certain other sea turtle populations worldwide (Hirth 1971; Balazs 1980). Both *O. branchiatus* and *O. margoi* have been documented on green turtles in Hawaii, but the former species is believed to be more prevalent (Balazs 1980). A quantitative survey on this subject is currently in progress by the authors.

The two species of leeches are easily distinguished in that *O. branchiatus* has seven pairs of branchiae and *O. margoi* has only five. The former species ranges in length from 3.5 to 11 mm, and the latter is 4 to 30 mm (Sawyer et al. 1975; Davies 1978; Lauckner 1985). Both species attach to soft skin surfaces of the axial and inguinal regions, as well as the neck, eyes and cloaca. In heavily parasitized turtles, yellowish mats of leech egg cases are commonly found cemented to the plastron and ventral surfaces of the neck and flippers.

Increasing numbers of green turtles afflicted with debilitating fibropapillomas (fibrous epithelial growths) have been recorded during recent years in the Hawaiian Islands (Balazs 1986; Dailey and Balazs 1987). A concomitant increase in parasitization by *Ozobranchus* has also been seen, especially on the turtles diseased with tumors. Fibropapillomas are highly vascularized, thereby affording ideal sites for leeches to attach. The relationship between *Ozobranchus* and fibropapillomas was first described by Nigrelli and Smith (1943).

Experimental prophylaxes on captive sea turtles parasitized by *Ozobranchus* have included the use of various toxic agents. Schwartz (1974) immersed captive loggerheads, *Caretta caretta,* and green turtles in copper sulfate solution; this treatment proved effective in eliminating *O. margoi* adults and their egg cases but induced increased swimming activity in the turtles. Concentrated topical iodine used by Schwartz (1974) was only temporarily effective. Davies and Chapman (1974) reported that 3 of 85 captive sea turtles heavily parasitized by *O. branchiatus* and *O. margoi* died several months after treatment with copper sulfate, but cause of death was not determined. They also applied 10% formalin directly to the leeches and their eggs, after which the turtles were left out of the water for 3 hours. This treatment, however, was not highly effective (Davies and Chapman 1974). At Sea Life Park in Hawaii, several topical treatments with isopropyl alcohol successfully eradicated *O. margoi* in a massive outbreak on captive green turtles, loggerheads and hawksbills, *Eretmochelys imbricata* (Sea Life Park unpublished data, 1978).

As with any toxic chemical treatment for parasites, there is the possibility of undesirable, acute or chronic side effects to the host. Consequently, the use of a benign therapy would be preferable, if such a treatment were available. On 9 August 1987, a lethargic juvenile green turtle, afflicted with tumors and measuring 55 cm in carapace length, was found stranded at Kailua Beach on the Island of Oahu, Hawaii. Numerous *O. branchiatus* were present on the turtle, especially on the ulcerated tumors protruding from the neck and eyes. Egg cases also were present in abundance. The turtle was subsequently held in a shaded seawater tank measuring 2.4 m in diameter and filled to a depth of 0.5 m. The turtle continued to survive in this holding facility, where it was fed chopped fish and squid on a daily basis. Incidental observations made during routine tank cleaning over the following weeks revealed that the leeches seemed to be negatively affected by rinsing with fresh water from a hose. As a result, systematic treatment and observations were conducted. Treatment consisted of draining the turtle's tank completely and filling it with fresh water. When treatment began on 23 September 1987, 120 leeches were attached to the turtle. The leeches reacted immediately to immersion in fresh water by rapidly crawling over the surface of the turtle. Within 30 minutes of soaking in fresh water, leeches began to fall off and were found dead on the tank bottom. After 90 minutes, 80 leeches remained on the turtle. The tank was then drained and refilled with seawater. The number of leeches on the turtle decreased progressively after the freshwater immersion. On the following day, only 35 of the initial 120 leeches remained. Only four leeches remained after 4 days; no leeches were present on Day 6.

Two weeks after treatment, leeches began to reappear, and the egg cases had changed from a dark to a light color. Close examination revealed that the lighter color represented newly hatched eggs. Consequently, it was concluded that the freshwater treatment had little or no effect on the egg cases and that additional treatments would be needed to completely rid the turtle of leeches as new ones hatched. Subsequent immersions were conducted on this turtle and on a second one also found stranded with a heavy infestation of *O. branchiatus.* Eventually, both turtles were completely freed of leeches, and no negative effects were seen.

The relative scarcity of *Ozobranchus* on healthy green turtles in Hawaii suggests that some natural mechanism exists to deter or eliminate these parasites. Hawaiian green turtles commonly use algal and sea grass foraging habitats, where freshwater discharges into the sea. Reduced salinities at these locations may aid in the control of *Ozobranchus* through hypotonic shock. According to Sawyer et al. (1975), both *O. branchiatus* and *O. margoi* occur exclusively in salinities over 30%. Another possibility in controlling leeches is that healthy turtles subject themselves to more frequent grooming by certain fishes at discrete underwater cleaning stations known to exist in Hawaii (Balazs 1980; Balazs et al. 1987). The special circumstance of adult green turtles sometimes basking ashore in Hawaii may also facilitate leech control through heating and desiccation (Whittow and Balazs 1982).

Future research should examine different levels of salinity and duration of immersion needed to effect mortality in leeches on captive turtles. These data may then be used to help explain, or predict, the natural means of parasite control by sea turtles in the wild and to refine a practical nonchemical treatment against leeches in captive turtles.

THE APPLICATION OF PLASTIC TAGS TO LEATHERBACK SEA TURTLES, *Dermochelys coriacea*

The loss of flipper tags applied to sea turtles is an issue of perpetual consternation to sea turtle biologists (Balazs 1982; Green, 1979; Hughes, 1982; Mrosovsky, 1976, 1983; Richardson et al., 1978a, 1978b). The application of tags that are readily shed renders the tagging effort futile and precludes the acquisition of data relative to annual nesting periodicities, inter-annual remigration schedules, population size and stability, and the movement of tagged individuals. Tags may show varying degrees of retention depending on the type of tag used and the species of sea turtle, as well as the geographic area frequented by the tagged individual. It is important, therefoe, to evaluate tagging methods in the specific context of species and locale.

In 1981, the U.S. Virgin Islands Division of Fish and Wildlife began the first systematic population and movement study of leatherback sea turtles (*Dermochelys coriacea*) nesting at Sandy Point National Wildlife Refuge on St. Croix. In 1982 we initiated a saturation tagging program to assess the fecundity, reproductive periodicity, and philopatry of individual turtles. Monel metal tags, successfully applied to nesting leatherbacks elsewhere (Hughes 1978; Schulz 1975; Siow 1977), were used at Sandy Point.

As the 1982 nesting season progressed, returning turtles showed carapaces abraded as a result of contact with the tag (presumably) inflicted during normal swimming activity. During nesting, coarse sand exacerbated abrasion damage. We attempted to mitigate tag-inflicted injury by applying monel tags "up-side-down" (so that the abrading cinch-tab faced upward). In addition, we applied flexible Riese plastic tags in order to assess both retention and carapace damage by these tags. Plastic tags are non-corrosive, highly visible, and show retention rates superior to that of monel tags on loggerhead sea turtles (*Caretta caretta*; Jim Richardson, pers. comm.), green sea turtles (*Chelonia mydas;* Green 1979), and east Pacific black sea turtles (*C. m. agassizi*; Alvarado et al. 1988).

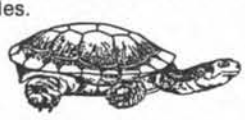
Gravid leatherbacks deposit as many as 10 clutches of eggs per annum at regular time intervals at Sandy Point (Eckert 1987). Thus, tag status is monitored on a continuing basis. This paper reports the retention rates of monel metal and Riese plastic tags on leatherbacks returning to nest on Sandy Point between 1981-1985. The potentially injurious effects of monel metal tags on leatherbacks are also discussed.

METHODS

During the nesting seasons (March-July) of 1981-1985, the 2.4 km nesting beach at Sandy Point was patrolled on foot nightly (1930-0550 h). Nesting turtles were tagged immediately following egg deposition. Tags were of two types: monel size-19 tags (National Band and Tag Co., USA) and Riese size-2 "Flexible Jumbo" tags (Dalton Ltd., UK). Tags were applied to the trailing edge of each foreflipper, ca. 20 cm from the body and 3.0 cm from the flipper edge. Fleshy areas too thick to accommodate the locking mechanism of the tag were avoided. Neither the monel nor the Riese tags were self-piercing. The former required that a single slit be made in the flipper with a small stainless steel knife; the latter required a circular hole be made with a leatherpunch. Monel tags were hand-inserted and clinched securely with a pair of channel-lock pliers. Riese tags were clinched with tagging pliers. Prior to 1982, turtles received a single monel tag. In 1982-1983, turtles received either a single Riese tag and two monel tags, or vice versa.

RESULTS

The mean and modal remigration periodicity of gravid leatherbacks to Sandy Point was two years (mean=2.07, sd=0.38, range 1-3 yrs). Remigrants comprised 14.3-45.0% of the nesting population annually. Twenty-eight remigrations involving 20 individual turtles were documented between 1981 and 1985, inclusive. Twenty-six plastic tags had been placed on 18 of the 20 remigrants. Only two of these turtles retained their plastic tags into a second nesting season: the first returned after one year of absence carrying one (of two) Riese tags, the second returned after one year of absence carrying two (of two) Riese tags. The turtle returning with two Riese tags shed them both during the course of the second breeding season, rendering the loss of plastic tags 25/26 (96.1%). Thirty-one monel tags had been placed on 19 of the 20 remigrants. The loss of monel tags from turtles returning after 1-3 years of absence was 5/31 (16.1%). These rates of loss differ significantly ($P < 0.05$; Proportion testing, Brase and Brase 1983).



DISCUSSION

Sea turtles shed monel flipper tags for a variety of reasons, including tissue necrosis, abrasion, corrosion, tearing, and improper application (Balazs 1982). With the exception of corrosion, the same problems can be expected to plague plastic tags. Abrasion and/or algal colonization obscured the numbers embossed into plastic tags applied to green sea turtles in the Galapagos Islands (Green 1979) and to loggerhead sea turtles in South Carolina (Talbert et al. 1980).

In the present study, the primary impetus behind the loss of plastic tags appeared to be localized tissue necrosis, which resulted in an enlargement of the placement hole and allowed the tag to slip through the flipper. This loss was rarely associated with a discernible pigment or mutilation scar (e.g., a tear or a hole). The flesh healed remarkably well; often the only "scar" was an internal silhouette of the original wound made visible by holding a flashlight against the underside of the foreflipper. Based upon this observation, we suggest caution in the interpretation of tag scars on leatherbacks. Nesting females often come ashore with holes of varying sizes in their flippers; in our experience, the vast majority of these do not represent the loss of a tag.

Siow (1977) has advocated use of plastic tags on leatherbacks, but Hughes (1974) and Fretey (pers. comm.) have discouraged it. After observing a 96.1% loss of plastic tags over a period of three years, we must concur with Hughes (1974) that, "all plastic tags proved useless in the long run as virtually every tag has ben lost." We conclude that (1) monel tags secured to the foreflippers of leatherback turtles can carve furrows in the carapace as a result of contact during swimming and nesting, leaving the animal bleeding and vulnerable to infection; (2) placing monel tags up-side-down (cinch-tab up) eliminates tag-inflicted carapace damage; (3) "Flexible Jumbo" plastic Riese tags effect no carapace damage but show very poor recovery rates; (4) tag loss on leatherbacks is rarely associated with an external pigment or mutilation scar.

The use of self-piercing titanium tags (both front and rear flipper placement) is currently under investigation as an alternative to monel or plastic tags for marking nesting leatherback sea turtles.

ACKNOWLEDGMENTS

Funding for this study was provided by EARTHWATCH (Watertown, Massachusetts), and the U.S. Fish and Wildlife Service to the U.S. Virgin Islands Division of Fish and Wildlife (Endangered Species Cooperative Agreement). Our gratitude is extended to the 291 EARTHWATCH members who provided us with continuous field assistance and without whom this research would not have been possible. An earlier draft benefited from comments made by A.D. Tucker.

FLUORESCENT POWDER — A METHOD FOR TRACKING REPTILES

It is often difficult to determine the daily movements of reptiles for calculating home ranges or evaluating microhabitat utilization. In the past, such information has been gained by 1) direct observation, 2) radioactive tags, 3) radiotelemetry, or 4) trailing methods (Ferner 1979). Direct observation is suitable only for conspicuous reptiles whose behavior is not affected by a nearby observer. Radioactive tags have the advantage of giving exact location information, but only one individual in an area can be distinguished and no information on movements between locations is obtained. Radiotelemetry can be used to detect the location of several individuals in one area, but there are size constraints and trade-offs between size of the transmitter, transmission range and duration of the signal. Trailing techniques (used primarily for chelonians) have the advantage of providing information on movements of animals in the absence of an observer, but they are limited to large animals with suitable behavior.

While studying the ecology of the island night lizard, *Xantusia* (=*Klauberina*) *riversiana*, on Santa Barbara Island off southern California, we needed information on microhabitat utilization and home range size and overlap. Radioactive tags were used to determine some aspects of home range and microhabitat use, but we needed more specific data on movements of individual lizards occupying overlapping home ranges.

Fluorescent powder has been used to track mice (Lemen and Freeman 1985), salamanders (Ireland 1973) and fish (Phinney 1969) and it also proved to be a good technique for island night lizards. We captured lizards in Sherman mammal traps and marked them by dipping them in a plastic bag containing about 50 cc of powder. Lizards were held by the head so that we could keep the powder out of their eyes and ear openings. To assure good adherence and coverage, we gently massaged the powder against the lizards from the outside of the bag thus covering the entire body except the head. The lizards were then released at the point of capture. The powder adhered well even though *X. riversiana* have smooth scales.

A portable ultraviolet light was used to locate the powder which rubbed off onto the ground and vegetation during the lizard's normal movements. Under ultraviolet light, the powder fluoresced brightly so that even a few specks could be seen. By laying out string along the routes traveled, we were able to map the areas of activity at a later time. It was helpful to use flagging tape to hold the string in place and also to indicate the color of the powder. It was not possible to determine direction of movement nor how many times a lizard followed a particular route.

We used six colors (red, orange, pink, green, chartreuse, and blue) to allow us to track different lizards in the same area (color names refer to the color under normal daylight). Unfortunately, under ultraviolet light, some of the colors were difficult to distinguish. For example, red and orange were very similar as were green and chartreuse. Blue was distinctive, but not particularly bright. With care, all pigments could be identified, but this sometimes entailed comparison with known colors. It helped to use a standard flashlight occasionally since some colors were more distinctive under incandescent lighting.

Powder continued to be deposited for at least five days. Since island night lizards are rather sedentary and use the same areas repeatedly, it was not possible to tell whether powder continued to be deposited after that time. Movements made during the first day or two showed up as distinct trails of powder. Areas of new activity became increasingly difficult to detect and generally required a careful examination of the ground and vegetation for occasional specks of powder. Brief trials with the western fence lizard (*Sceloporus occidentalis*) suggested that powder adheres better to lizards with keeled scales and hence it may be possible to detect new movements for a longer time.

The use of fluorescent powders is a good technique for certain species of reptiles. Since the powders are very bright, they may not be appropriate for conspicuous, diurnal species which might suffer increased predation or intraspecific interactions. Also, the powder might influence heat absorption and thus affect thermoregulatory behavior. These problems could be reduced by applying powder to only the ventral and perhaps lateral parts of the animal. For secretive, nocturnal or semifossorial species the technique works well with a minimum of influence on normal behavior. Several lizards were captured 7-10 days after marking. Nearly all of the powder had rubbed off and none of the lizards showed any ill effects from marking.

Fluorescent powder (Series R-103-G) was obtained from Radiant Color (2800 Radiant Ave., Richmond, California 94804). In 1987, these pigments cost about five dollars per one pound can. One pound would be sufficient to mark at least 100 animals. Our ultraviolet light was a Blak-Ray longwave ultraviolet lamp (ML-49) from Scientific Marking Materials (P.O. Box 24122, Seattle, WA 98124). It sells for about $130. The light runs on two 6-volt lantern batteries. The less powerful UV lights which use C or D size batteries do not provide enough light for reliable tracking.

Since ultraviolet light (both long and short wavelengths) can damage the eyes, it is prudent to avoid looking directly at the light. Glasses which filter UV light are available from Scientific Marking Materials.

ACKNOWLEDGMENTS

The National Park Service provided transportation to the island and financial support for the research. Joan Fellers, Martin Rosenberg and two anonymous reviewers offered useful comments on the manuscript.

BURROW-TO-TORTOISE CONVERSION FACTORS: COMPARISON OF THREE GOPHER TORTOISE SURVEY TECHNIQUES

Gopher tortoise (*Gopherus polyphemus*) burrows are generally the most conspicuous indication of tortoise presence in an area, and burrow counts can serve as an index to animal numbers. Accuracy of these censuses depends on reliable survey technique and a suitable correction factor relating tortoise number to burrow number.

Traditional gopher tortoise censusing techniques use strip transects to survey an area for burrows and count the number of burrows in each of three or four activity classes, based on field sign. Auffenberg and Franz (1982), Kushlan and Manzotti (1984), Logan (1981), Burke (1989), and many unpublished surveys estimated tortoise numbers by multiplying the sum of "active" and "inactive" burrows by 0.614. This correction factor is based on results of a long-term study of 122 burrows in Alachua County, Florida (Auffenberg and Franz 1982).

Review of recent studies (Table 1) shows considerable variation in reported correction factors, ranging from 4 to 75% of active and inactive burrows, and 21 to 98% of active burrows. Variation may be attributed to differences in surveyors' evaluations of burrow activity status or variation in gopher tortoise burrow use, or both. Breininger et al. (1986), based on studies in different habitats and seasons with an underground camera system, cautioned that correction factors should be determined on a site-specific basis. A number of reasonably reliable techniques may be used to establish gopher tortoise burrow occupancy (Burke and Cox 1989). Cox et al. (1987) suggested that, depending on survey goals, trapping, using an underground camera system, the activity classification system used by Auffenberg and Franz (1982) and the "stick" method (Hallinan 1923, Burke and Cox 1989) may be acceptably reliable techniques.

MATERIALS AND METHODS

I used the 0.614 correction factor, a stick survey, and a portable, motorized car carrying a video camera ("Burrow Bug," Moe Devices, 2968 Elsie, Toledo, Ohio 43613) to compare tortoise/burrow correction factors. The study site was the Wade Tract Preserve, a privately owned 80 ha old-growth longleaf pine forest in Thomas County Georgia. This forest, managed by Tall Timbers Research Station, is representative of conditions over much of the southeastern United States prior to European settlement (Platt et al. 1988). During a thorough June 1988 survey, Tall Timbers personnel found 199 active and inactive burrows, and occupancy of each was tested using the stick method. All burrows were assigned an identifying number, and using a random number generator, 12 active and 10 inactive burrows were randomly selected and examined using the video camera. Results are displayed in Table 2.

DISCUSSION

Based on the results from this study (Table 2) and others (Table 1), the generalized use of any specific correction factor such as that of Auffenberg and Franz (1982) cannot be supported. Rather, occupancy of tortoise burrows likely differs by season or habitat types, or in different parts of the range, especially considering regional and local variation in the harvesting of tortoises for food. Seasonal changes in burrow use have been documented (McRae et al. 1981), and while some tortoise populations may not burrow at all (Auffenberg 1969), others may use seven or more burrows per tortoise (McRae et al. 1981).

Spillers and Speake (1989) in Alabama, and Lohoefener (1982) in Mississippi reported correction factors of ca. 0.6 times the number of *active* burrows. Neither study reported sample sizes or considered habitat, seasonal or other sources of variation. In addition, Lohoefener did not state how occupancy was determined. Unfortunately, Cox et al. (1987) and others have misinterpreted the results of these studies as supporting the general use of the conversion factor calculated by Auffenberg and Franz (1982), who counted both active and inactive burrows. Clearly, omission of inactive burrows from calculations can significantly alter census results. Also, distinguishing between active and inactive activity classes can be difficult, even for trained field workers. Breininger et al. (1986) created an additional activity class, "maybe active." Probably the most reliable approach is to group active and inactive burrows, rather

Table 1. Examples of reported correction factors

than try to distinguish between them.

This study was designed to compare three techniques, not to estimate population size. However, the results show that use of a direct technique can result in a much lower estimate of population size than indirect techniques. While indirect methods such as the stick survey are relatively easy and inexpensive, they are probably inaccurate and their error rate is unknown. Stick surveys require repeat visits to each marked burrow, and numerous factors could alter the ratio of tortoises present to burrow mouths disturbed. These techniques may be appropriate for coarse estimates, especially when time is limited. They are probably most reliable when used to compare sites for which factors affecting burrow use are similar—for example, to detect population changes over time in the same habitat.

Breininger et al. (1986) and Spillers and Speake (1989) developed camera systems to census gopher tortoises. Their systems are more expensive (approximately $15,000), heavier, and bulkier than the Burrow Bug, which costs approximately $5,000, and along with battery, can be carried by one person all day.

Like some of the systems used by Breininger et al. (1986) and Spillers and Speake (1989), the Burrow Bug I used was too large to fit into any burrows smaller than those of small adults. However, because most gopher tortoise populations are mainly composed of large adults, this was rarely a problem. It also cannot be operated in flooded burrows. The accuracy of censuses using the Burrow Bug also depends on tortoises being in their burrows when survey is done. Therefore, it may be particularly useful during winter months, when assessment of activity signs and use of the stick method (which require tortoise activity) are particularly unreliable. Despite high tortoise densities, they are very rarely seen above ground at the Wade Tract Reserve. Unlike the situation in some other areas, tortoises at the Preserve are apparently very wary of humans and stay below ground whenever people are around, even during warm months.

Once mechanical problems were resolved, an average of six minutes was required to set up and view the interior of each burrow. This is probably too slow to thoroughly survey a large area, but if random sampling were used, reliable site-specific correction factors could be derived. I only viewed the interiors of ca. 10% of the available burrows, but the system could produce an accurate population estimate if more burrows were surveyed. Video systems also can provide information on the presence of commensal species in burrows, and could document multiple occupancy by the tortoises, which indirect methods cannot indicate. Another use might be to investigate burrow use by uniquely marked individual tortoises. When tortoises must be captured, the system could be used to limit capture effort only to occupied burrows. I have also used the Burrow Bug successfully to observe burrows of desert tortoises (*Gopherus agassizii*).

ACKNOWLEDGMENTS

This study would not have been possible without the ingenuity, skill, and support of the staff of Moe Devices. I also thank Dr. Sharon Hermann and other Tall Timbers Research Station staff and volunteers who supported and assisted this work. J. Cox, D. Franz, S. Hermann and anonymous reviewers thoughtfully reviewed the manuscript and made numerous helpful comments.

GEOGRAPHIC DISTRIBUTION

See Herp Review *20(1) for author's instructions.*

NEW TEXAS HERPETOLOGICAL DISTRIBUTION RECORDS FROM THE UNIVERSITY OF TEXAS AT ARLINGTON COLLECTION OF VERTEBRATES

The recent publication of Dixon's (1987) *Amphibians and Reptiles of Texas* has been a milestone in defining the distributions of Texas species. Nevertheless, Texas has a diverse geography, encompasses considerable territory and additional geographic records will continue to be discovered. The appearance of Dixon's excellent work on Texas has made possible an evaluation of that material housed in the University of Texas at Arlington Collection of Vertebrates (UTACV) representing new county records. Some of these new county records represent range extensions and these are indicated where appropriate. All Serpentes were verified by M.E. Dorcas, and all other specimens were verified by J.S. McCord, Jr., unless otherwise indicated.

CAUDATA

SIREN INTERMEDIA (Lesser Siren). Smith Co: Tyler, Caldwell Zoo grounds. 10 April 1985. W. W. Lamar, J. Stout and K. Hovey. (UTACV A-19003).

AMBYSTOMA TIGRINUM (Tiger Salamander). Cherokee Co: Mixon. 1985. R. Robinson. (UTACV A-23521).

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). Wood Co: FM 312, 3.2 km S of State Hwy 154. 13 June 1984. A. Loller. (UTACV A-13595).

ANURA

SCAPHIOPUS COUCHI (Couch's Spadefoot). Moore Co: Blue West Recreational Area, on North shore of Lake Meredith. 6 August 1986. T. L. Hibbits. (UTACV A-20845).

SYRRHOPHUS GUTTILATUS (Spotted Chirping Frog). Pecos Co: State Hwy 285, 47.9 km N of State Hwy 285-U.S. Hwy 90 junction. 6 October 1984. J. S. McCord, Jr., J. M. Johnson, P. J. Bradley. Verified by J. A. Campbell. (UTACV A-17418). Extends range ca. 48 km Northeast of Brewster county.

HYLA CRUCIFER (Spring Peeper). Bowie Co: North Mill Creek, U.S. Hwy 259, ca. 7 km N of U.S. Hwy 259-F.M. 2735 junction. 2 March 1986. J. S. McCord, Jr. and D. Roberts. (UTACV A-18585).

PSEUDACRIS STRECKERI (Strecker's Chorus Frog). Johnson Co: junction of Ham Creek and Brazos River. 15 May 1985. M. Burleson. (UTACV A-15900-15901).

BUFO PUNCTATUS (Red-spotted Toad). Crane Co: 8.4 km SSE of jct of U.S. Hwy 385 and State Hwy 329. 18 October 1986. G. Ferguson, M. Ferguson, D. Ferguson, A. Landwer and J.S. McCord, Jr. (UTACV A-25392-25394).

BUFO SPECIOSUS (Texas Toad). Jim Hogg Co; Randado, on State Hwy 16. 25 June 1981. J. P. Karges. (UTACV A-9099). Zapata Co: FM 3169, 15.5 km NE of junction of FM 3169 and U.S. Hwy 83. 18 May 1980. J. P. Karges. (UTACV A-8515).

RANA AREOLATA (Crawfish Frog). Henderson Co: 3.7 km N of Malakoff. 16 March 1957. W. F. Pyburn. (UTACV A-294).

RANA CATESBEIANA (Bullfrog). Randall Co: 3.2 km N of Canyon. 19 December 1963. J. R. Glidewell. (UTACV A-2970).

GASTROPHRYNE CAROLINENSIS (Eastern Narrowmouth Toad). Delta Co: Cooper Dam site, 12.9 km NE of Commerce. 30 April 1983. T. L. Hibbits. (UTACV A-13582).

TESTUDINES

CHELYDRA SERPENTINA (Snapping Turtle). Jasper Co: Angelina National Forest, 4.8 km W of U.S. Hwy 69 on dirt road to Bouton Lake. 17 March 1979. J. P. Karges. (UTACV R-8415). Llano Co: 12.8 km N of Llano, Houston Ranch. 19-21 March 1985. Natural History Class (University of Texas at Arlington). (UTACV A-17769). Rockwall Co: Rockwall. 9 February 1979. J. Boyd. (UTACV R-8413). Taylor Co: Summerhill Road jct with Double Lazy "J" Ranch. 18 June 1983. J. Joy. (UTACV R-12830).

KINOSTERNON FLAVESCENS (Yellow Mud Turtle). Anderson Co: Engeling State Wildlife Management Area. 18-20 April 1986. J. S. McCord, Jr. and M. E. Dorcas. (UTACV R-17771). Comanche Co: U.S. Hwy 377, 27.7 km SW of Dublin. 16 May 1979. J. A. Campbell, L. S. Farris and J. P. Karges. (UTACV R-9179). Red River Co: Big Pine Creek, ca. 3.2 km Northwest of Manchester. 5 May 1979. J. R. Glidewell. (UTACV R-11222).

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). Franklin Co: 8.8 km N of Mount Vernon. 6 April 1975, J. R. Glidewell. Verified by M. E. Dorcas. (UTACV R-5164).

KINOSTERNON SUBRUBRUM (Eastern Mud Turtle). Franklin Co: 8.8 km N of Mount Vernon. 6 April 1975. J. R. Glidewell. Verified by M. E. Dorcas. (UTACV R-5164).

STERNOTHERUS CARINATUS (Razorback Musk Turtle). Camp Co: Ferndale Lake, 11.2 km SE of Pittsburg. 4 June 1979. J. R. Glidewell and P. J. Prete. (UTACV R-11188-1190). Extends range ca. 34 km NW of Marion county.

DEIROCHELYS RETICULARIA (Chicken Turtle). Van Zandt Co: N of Ben Wheeler on Neches River. August 1987. J. Isaacs. Verified by M. E. Dorcas. (UTACV R-22394).

GRAPTEMYS KOHNII (Mississippi Map Turtle). Franklin Co: Sulfur River, 0.8 km E of State Hwy 37 bridge. 30 May 1986. J. Cover, D. McCaffey and D. G. Barker. Verified by J. S. McCord, Jr. (UTACV R-17053). Hill Co: Nolan River, just below Blum. Late June 1985. M. Burleson. Verified by M. E. Dorcas. (UTACV R-22254).

PSEUDEMYS CONCINNA (River Cooter). Cooke Co: Moss Lake, 19.3 km NW of Gainsville. 16 July 1977. J. R. Glidewell. (UTACV R-11253). Extends range ca. 37 km N of Denton county. Johnson Co: Mill Creek, 0.2 km N of County road 1108. 13 May 1979. G. Carl and R. Stevens. (UTACV R-8737). Extends range ca. 42 km S of Tarrant county.

PSEUDEMYS TEXANA (Texas River Cooter). Taylor Co: Abiline, Dyess Air Force Base. 13 August 1983. (UTACV R-12966).

TERRAPENE ORNATA (Western Box Turtle). Collin Co: 8 km SE of Blue Ridge. 10 August 1976. L. C. Fitzpatrick, J. L Hughes and J. R. Glidewell. (UTACV R-11230).

TRACHEMYS SCRIPTA (Slider). Camp Co: Ferndale Lake 11.2 km SW of Pittsburg. 4 June 1979. P. J. Prete and J. R. Glidewell. (UTACV R-22598-22605). Hill Co: Nolan River, ca. 0.8 km N of junction of Brazos River and Nolan River. 13 September 1987. T. M. Kubin. (UTACV R-19361). Both verified by M. E. Dorcas.

SAURIA

SCELOPORUS OLIVACEOUS (Texas Spiny Lizard). Hamilton Co: Sand Branch Creek at U.S. Hwy 281 and FM 221. 21 March 1987. J. S. McCord and M. E. Dorcas. (UTACV R-18480-18481).

EUMECES OBSOLETUS (Great Plains Skink). Jeff Davis Co: 1.6 km S of Fort Davis. 9 February 1965. Thomas R. VanDevender. (UTACV R-27).

EUMECES TETRAGRAMMUS BREVILINEATUS (Short-lined Skink). Parker Co: 6.4 km NW of junction of FM 113 and U.S. Hwy 180. 12 August 1986. J. Forester and J. S. McCord, Jr. (UTACV R-16437-16439).

NEW FROM KRIEGER !!

SNAKES OF THE WORLD
by Kenneth L. Williams & Van Wall

VOL. 1: Synopsis of Snake Generic Names
Ed. 1989 244 pp $31.50
ISBN 0-89464-215-4

VOL. 2: Synopsis of Living and Extinct Species
Orig. Ed. 1990 $33.50
ISBN 0-89464-216-2

VOL. SET
Orig. Ed. 1990 Pre-Pub. $59.50
ISBN 0-89464-302-9

This long awaited work comprises an alphabetical list of living and fossil generic and subgeneric snake names, living and extinct species, emendations, and spelling variations. Type species designations are provided for all original descriptions. Each name is furnished with its family allocation (if valid) or senior synonym (if invalid), and bibliographic references are included. A literature review is presented for controversial names. An invaluable reference for the amateur and professional zoologist, natural history museums and libraries. Bibliography includes references that include original description of all valid species and references used in text.

BIOMEDICAL AND SURGICAL ASPECTS OF CAPTIVE REPTILE HUSBANDRY
by Fredric L. Frye
2nd Ed. 1990 $289.50
ISBN 0-89464-310-X

This second edition is enhanced by the addition of much new and previously unpublished information. Two chapters that have been included are written by recognized experts in their fields of interest, Dr. Alex Rubel of Zurich, and Dr. Douglas Mader. Dr. Rubel contributed a monograph on radiography, and imaging. Dr. Mader wrote a monograph on antibiotic therapy and discusses the relevance of metabolic scaling of antibiotic dosages. Other chapters include an introduction to herpetology, captive husbandry, a guide to nutrition, infectious diseases, antibiotic therapy, conditions related to the captive environment, radiology and imaging, hematology, non-hemic parasitology, ophthalmic disorders, reproductive disorders, developmental anomalies, anesthesiology, surgery, comparative histology, euthanasia, necropsy techniques, and pathologic conditions. More than 1,800 color photos are included.

Please write for further information.

When ordering, please add $4.00 for first book $1.00 each additional to cover shipping charges.

BOOK REVIEWS

Contributions to the History of Herpetology, edited by Kraig Adler. 1989. 202 pp, frontis. (col.). 149 photos, Soc. Study Amphs. Repts. (SSAR·Publications Secretary Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103 U.S.A.) Clothbound $20.00.

By now the herpetological world has seen enough of the work of Kraig Adler to be sure that anything edited or written by him will exemplify exacting and exhaustive scholarship, and will bear an unmistakable touch of class as well. The present work is no exception.

Elegance is provided by the striking color frontispiece of John Edwards Holbrook; by the inspired title page in color, bearing a replica of a compartmented, 1584 anglosaxon border; by the 149 portraits of the workers of the past chosen for biographical sketches (only 3 lack portraits); by replication of the signatures of every biographee (many appearing on the book's cover as well as with the appropriate biographic account); by the insertion as a frontispiece to Adler's own article of a facsimile of a letter written by J.E. Holbrook in 1837 to a potential collector, together with a transcription (the original is difficult to decipher) and brief notes on Holbrook; and of the black-margin divider readily separating the three articles contained in the book. The two-column, 8½ x 11 in format provides superior (over a smaller size) economy of space, ease of reading and adequate space for illustrations, all without incurring the filing problems that a larger size would pose.

The book contains three sections. The first, by Adler, "Herpetologists of the Past," occupies 141 pages, with its index. The second, by John S. Applegarth, "Index of Authors in Taxonomic Herpetology," cover 36 pages, and the third by Ronald Altig, "Academic Lineages of Doctoral Degrees in Herpetology," 24 pages. All are exhaustively researched in spite of overwhelming difficulties of pursuing each lead separately, for there are no previous compendia from which to draw. Altig's article, for example, accounts for an incredible 1446 holders of doctoral degrees from institutions in 23 countries. Applegarth's list includes all authors, with birth-death dates, countries and pertinent orders, having named one or more taxa among living families of amphibians or reptiles, or having had one or more taxa named for them as well as having published at least one title in the field. That staggering task included 2506 persons, including almost all who worked in *any* field of herpetology through 1920, but a progressively lesser per cent since then. At one time the history of herpetology was the history of its taxonomy, and not much more; that is far from the case now or for the past several decades.

Much remains incomplete in both the Applegarth and Altig compilations—especially dates for the former—as the authors were well aware, asking for corrections and additions.

A historian's touch is obvious in Adler's section, containing as it does an enormous amount of detail about the lives, influence and contributions of each of the biographees, all deceased. In the process, a total of 590 people are cited, according to the index. Sources of biographical material are meticulously cited for each account, although only primary sources were available for some, and were additionally explored for many others. Thus much information appears in this book for the first time. Most accounts are less than a page long; a few exceed one page, and only one (for E.D. Cope) exceeds two pages. The arrangement is more or less chronological, based on dates of peak of influence, hence is somewhat arbitrary. Most impressive is the cosmopolitan choice of biography; Adler scrupulously attempted to avoid provinciality, limiting U.S. biographees to 38. The remaining 114 are broadly international.

In like fashion, Adler carefully avoided any pejorative comments, although the importance of the work of each person included was invariably discussed.

Each of the three sections of this book constitutes, then, an important original contribution to the history of herpetology, and is an outstanding credit to the meticulous diligence of its author. The book should be regarded as an essential component of every herpetologist's library, to be savored in utmost appreciation for the contributions of those who have gone before, and upon which we now build. Nothing else in herpetology so leads us to reflect upon how much others have contributed to the whole that is the heritage we and those yet to come benefit from.

Ecology of Reptiles, by H.F. Heatwole and J. Taylor. 1987. Surrey Beatty & Sons, 43 Rickard Road, Chipping Norton, NSW 2170, Australia. ISBN 0 949324 14 0. 325 pages including 48 figures, 20 tables, 36 Australian species on 6 color plates, and about 1150 references for $44.00 in hardcover.

This book is a second edition of Dr. Heatwole's 1976 contribution to the Australian Ecology Series. The second edition contains five more chapters, is 150 pages longer, and has over 650 more references than the first edition. The scientific literature is updated through much of 1985, with some 1986 references. Among the several ambitious goals of the book are (1) to provide college students, teachers, scientists, and conservationists

with a "basic conceptual and factual background" in reptile ecology, and (2) to stimulate insightful research. The book focuses on research results on Australian reptiles, but the majority of citations are from research on non-Australian reptiles; most of the important review publications on the many facets of reptile ecology are also cited.

The chapters are: (1) Australia's Environment and Distribution of Reptiles, 20 pages; (2) Thermal Ecology, 75 pages; (3) Water Relations, 23 pages; (4) Salt as an Ecological Factor, 8 pages; (5) Activity Cycles, 8 pages; (6) Feeding Ecology, 6 pages; (7) Reproductive Ecology, 19 pages; (8) Population Dynamics, 27 pages; (9) Ecological Energetics, 8 pages; (10) Social Organization, 11 pages; (11) Reptilian Assemblages, 41 pages; with a 5 page Appendix on Australia's Reptilian Fauna. The exceptional lengths of chapters 2 and 11 probably reflect both the senior author's familiarity with those topics (see the Bibliography) and the preponderance of research in reptile thermal ecology in earlier decades.

Such uneven topical treatment, as indicated by the extreme brevity of some chapters, is bound to disappoint most readers. Particularly irksome to me is the chapter on feeding ecology. Given my opinion that food acquisition mode is the single most important adaptive syndrome in an animal, I find the four and one-half pages of text, one figure, and one table in the chapter stunningly inadequate. But, even in the short chapters, most of the important publications, or reviews of those publications, are at least mentioned.

The authors stated in the Preface to Second Edition that "the literature on reptile ecology is becoming voluminous and unwieldy." With this assessment it is no surprise that the information in each chapter is not well integrated with information of other chapters. Even such obviously related chapters as Reproductive Ecology (chapter 7) and Ecological Energetics (chapter 9) are poorly integrated. The short section on evolutionary strategies of life history in the end of the eclectic chapter 8, on population dynamics, likewise should have been woven in with material of chapters 7 and 9.

The first chapter, regrettably, did not contain major themes that could have set a coherent, cohesive tone for the book. For example, questions about Australian reptile species diversity and individual species distribution and abundance (venerable natural historical issues) could have been showcased immediately in the first chapter. But the requisite tables, graphs, and maps of vegetation types and climatic patterns are missing; and the related histories of reptiles, climate, and vegetation are not well integrated. The chapter on reptilian assemblages (one of the better chapters) would have been a good place to assess and summarize themes initiated in earlier chapters.

Although *Ecology of Reptiles* does not have an effective thematic approach like S.D. Bradshaw's *Ecophysiology of Desert Reptiles* or Eric Pianka's *Ecology and Natural History of Desert Lizards*, it certainly has a more comprehensive treatment of reptile ecology than either of these two books. It seems, however, that snakes, chelonians, and crocodilians are underrepresented in most chapters. The authors also missed opportunities to make many valuable comparisons among reptilian taxa (orders through subspecies), and among reptiles with differing body sizes, food-acquisition modes, and habitat types. Moreover, I have the strong impression that recent theoretical and empirical advances, trends, and disputes in animal ecology have been only weakly addressed in *Ecology of Reptiles*.

Some of the research results on Australian reptiles that were chosen as examples came from honour's theses and other unpublished works, or were not as useful as some publications of exemplary research on reptiles from other continents. In these cases, the reader would have been better served with the finer examples of published research that are easier to obtain and examine than theses. The Australian bias is well illustrated in a quizzical phrase that I bumped into frequently in the text: "an American lizard." One can ascertain from this phrase neither the continent, climatic zone, nor habitat-type occupied by the animal, nor even the lizard's taxonomic family. On the whole, however, the emphasis on Australian reptiles should prove useful to herpetologists already familiar with the literature on non-Australian reptiles.

A more annoying problem for me was the authors' frequent lack of discrimination among studies when they cited evidence for particular phenomena. Papers with essentially anecdotal information or estimated parameters were not differentiated from papers with statistically analyzed data. And more than a few papers are what I consider to be miscited (as is one of mine) or curiously interpreted. Careful presentation of unanswered questions and contrasting hypotheses, and evaluation of evidence bearing upon questions and hypotheses are rare commodities, particularly in the shorter chapters. Despite the problems typical of textbooks—an often vague, encyclopedic review-paper approach, and inadequate critical evaluation of data and ideas—*Ecology of Reptiles* is worth having as a reference (over 1150 citations) and a tentative guide to (Australian) reptile ecology.

Herpetological Collecting and Collections Management, by John E. Simmons. 1987. SSAR Herpetological Circular No. 16. 70 pp. $6.00. Order from: Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, St. Louis, MO 63103, USA.

The same SSAR series that brought us George Pisani's excellent *Guide to Preservation Techniques for Amphibians and Reptiles* (Pisani 1973; Pisani and Villa 1974), now includes another very useful methodology volume. In addition to reviewing preserving techniques, *Herpetological Collecting and Collections Management*, by John Simmons, covers methods and materials used before preservation, during collecting, and after preservation, in collection management. Simmons' well-organized and complete treatment provides in-depth coverage of topics from recording frog songs to rehydrating alcoholic specimens. About one-fifth of the volume covers collecting and preserving methods, three-fifths is a collection management guide and the final fifth is an extensive bibliography.

In the first section the author treats such subjects as how, where and what to collect, how to document the collection, and what collecting gear and supplies to carry into the field. His suggestions include hints on photographic and sound recording equipment and supplies. Fluid preservation of specimens is covered in some detail but other methods, such as skeletonizing, and clearing and staining are treated via lists of references. No reference for preparation of specimens destined for electron microscopy was included; Dawes (1988) is suggested.

Under killing methods it would have been useful to mention freezing as the best method for killing specimens intended for skeletons, and isopropyl alcohol as a cheap, readily available and unrestricted alternative to nembutal. When injected into the brain of reptiles through the optic foramen isopropyl gives rapid results and leaves specimens totally relaxed within minutes.

The majority of Simmons' volume is dedicated to collection management. He briefly reviews the history and purpose of systematic collections, suggests what types of facilities are required, and outlines how to correctly undertake a long list of procedures normally used in herpetological collections. He discusses choosing a preservative, accessioning and cataloging processes, development of indexes, handling of types and special collections, and making and receiving loans. A series of miscellaneous but important topics including updating nomenclature, topping up alcohol and rehydrating specimens is buried in the section on loans; more attention to headings would have given these topics better visibility. The text ends with some guidelines for collection growth and the evaluation of collection management.

Although the coverage of collection management tasks is complete and I agree with the methodologies suggested, a set of priorities for these tasks would also have been useful. Most collections are short on help and may not be able to attend to all of the tasks outlined. In these less-than-ideal situations special attention must be paid to the top two priorities of the collections manager. He/she must be certain that no specimen deteriorates and that no specimen is separated from the data available for it. I was raised under the philosophy that specimens should remain physically associated with their data and therefore strongly support the use of data tags. Simmons feels that data tags are clumsy and will damage specimens. This type of damage will be minimized by following a few simple rules: (1) always tie a knot in the tag string about three-fourths of an inch from the tag so the tag can be turned free of the specimen, (2) always lie the tag under small specimens when packing them for shipping, (3) never jam specimens into jars containing alcohol and other specimens (instead, place

specimens with tags up in empty jars and then add alcohol) and (4) never tie data tags to very small specimens but handle them as suggested by Simmons for catalog tags on pages 32 and 33.

Simmons suggests that these larger tags are prone to disintegration; this is not the case if they are printed on paper of the quality used for catalog tags (see p. 35) and are not used as handles to pick up specimens. There are several advantages to having data tags on specimens: (1) it eliminates the necessity of having to keep adding data to jar labels (this usually means rewriting the whole jar label) and allows breakdown of full jars without the need to write out all of the data on the labels, (2) the data go out with specimens on loan without any extra effort, and (3) depending on the amount of data included on the jar label, it may reduce the time that ever-precious catalogs will have to spend in the collection room exposed to alcohol spills. Under this system, jar labels show only the most general geographic origin of all of the specimens in that jar: country or country and state for foreign material, state or state and county for domestic material.

In the section on loans, Simmons suggests using Parcel Post to ship specimens. In most cases library rate is even less expensive.

As Simmons points out in his introduction, there are no standardized procedures for managing herpetological collections. In this volume he has attempted to set some standards, and high ones at that. Adherence to the methods he suggests would ensure that a collection would be maintained in an excellent condition and in a state of maximum readiness for researchers. All collections managers should definitely aspire to these ideals, and no collection or series collector should be without a copy of this guide.

The Amphibians and Reptiles of Missouri, by Tom R. Johnson. 1987. Missouri Department of Conservation, P.O. Box 180, Jefferson City, MO 65102-0180, USA, xii + 368 pp., 258 color photos, 109 maps. Soft cover, $13.00; hard cover, $16.00 (Missouri residents add 81¢ or $1.00 sales tax, respectively).

Missouri joins the roster of states having an authoritative recent summary of its herpetofauna. The book fulfills a need in providing an updated coverage of both amphibians and reptiles. Johnson's book is one of the best. It should be a staple reference for years to come and used considerably by anyone having an interest in Missouri's amphibians and reptiles.

Johnson's book includes sections that are typical of state books on amphibians and reptiles, but there are some added features of interest to the professional herpetologist. The author's artistic talent pervades the text with black and white drawings and excellent color photographs in the accounts of species, as well as a watercolor print of the Three-toed Box Turtle that adorns the front cover.

A preface by Roger Conant is preceded by a table of contents and two pages of acknowledgments. A brief history of Missouri herpetology (3 pp.) provides biographical sketches of Julius Herter, Sr. and Paul Anderson. Five physiographic provinces are recognized in Missouri (6 pp.), are discussed with colored photos of each, and each is delimited on a county map of Missouri. A methods and procedure section (2 pp.) is followed by a checklist (4 pp.) of 107 species (131 species and subspecies, 23 of salamanders, 26 frogs and toads, 21 turtles, 11 lizards, and 50 of snakes).

Illustrated keys (pp. 16-35) to Missouri's species of salamanders (20), frogs and toads (22), turtles (17), lizards (10), and snakes (38) precede the species accounts (286 pp.). Species are arranged phylogenetically and introduced by general comments relating to respective families and to major groups of the herpetofauna (salamanders—frogs and toads, turtles, lizards, and snakes); family comments are embellished by a black and white sketch of a representative Missouri species. Myths about snakes (p. 226) precede the species accounts. Each species is discussed under subheadings of Description, Habits and habitat, Breeding, and Missouri Distribution; many species accounts have additional subheadings of Remarks or Subspecies. Excellent color photos accompany each species account, and presumably all (some not identified by county origin) are specimens from Missouri (except a Kansas specimen of *Trionyx muticus* by Joseph T. Collins).

In addition to adults (often more than one photo to show characteristics), accounts of some species may include color photos of amphibian egg masses, tadpoles, reptile eggs, hatching young, and juveniles; the account of the gray tree frog includes sonograms of syntopic Missouri specimens of *Hyla versicolor* and *H. chrysoscelis*. Shaded distributions of each species (and subspecies) are depicted on a county map of Missouri with documentation for known county records indicated by single black dots (open circles indicate no voucher specimens).

Following accounts of species is an annotated list of three salamanders, two anurans, three lizards, and five snakes of possible or of questionable occurrence in Missouri (3 pp.). A section for identifying selected tadpoles (7 pp.) includes labelled illustrations, and descriptive comments with accompanying line drawings (left side of body-tail, and oral disc) of 11 species.

Finally, a Glossary of 79 terms precedes the Bibliography, which is subdivided into two parts—general works (279 references) and Missouri references (109 references). In a terminal index (pp. 359-367) common and scientific names are cross-indexed under all the different appellations with principal accounts of species in bold-face type. Missouri counties are named on a map on the last page (hardcover) or inside of back soft cover. A photograph and vita sketch of the author fill the outside back cover.

There is little to quibble about regarding substantive information. The use of *Nerodia rhombifer* (instead of *rhombifera*) is novel. *Trionyx spinifer* is used throughout text, but *T. spiniferus hartwegi* is employed in the checklist. I do not understand the meaning of the third alternative feature used in couplet 12 in the key to turtles (p. 26) in regard to "first marginal. . .ventral." Only three (not four) species of trionychid turtle occur in the U.S. (p. 189). There are some errors, misspellings, and omissions—I discovered only 13 misspellings and two text citations to references with incorrect year (p. 93, Wright and Wright 1942 = 1949; p. 157, Mahmoud 1969 = 1968), but many instances of a, b, etc. not accompanying the year in text citations when author published more than one paper the same year (e.g., p. 121, Fitch 1956 and Nelson 1972). The bibliography (although not a Literature Cited)

FIRST CONGRESS POSTER

The official poster for the First World Congress of Herpetology held in Canterbury, U.K., in September, is now available for sale. The print measures 11 1/2 by 15 inches and includes a full-color drawing of an Eastern Box Turtle (*Terrapene carolina*), from a watercolor by David M. Dennis. The poster was issued as part of SSAR's salute to the congress and printed in an edition of 1500 copies. About 500 copies remain for sale, at $8.00 each or $5.00 in quantities of 10 or more, postpaid.

Address orders to the SSAR Publications Secretary, Robert D. Aldridge, Department of Biology, St. Louis University, 3507 Laclede, St. Louis, Missouri 63103, U.S.A.

seems to contain some references not cited in text (e.g., Lodato, 1983). However, there are 11 text citations to references that do not appear in either of the two sections of the bibliography.

Despite these minor flaws the book is of high quality and scholarship, exceptional in treatment, admirable in production, and is highly recommended. The Missouri Department of Conservation and author should be proud of this book, and thankful to have been able to publish it at a most reasonable price. I am glad to have this book.

World Checklist of Threatened Amphibians and Reptiles, by Brian Groombridge. 1988. Nature Conservancy Council, Peterborough, United Kingdom. 138 pp. Soft cover. £16.00 (ca. $27.00).

The stated purpose of this book is to "provide a summary of basic information on all species listed in CITES (Convention on International Trade in Endangered Species of Wild Fauna and Flora) or appearing in the IUCN (International Union for the Conservation of Nature and Natural Resources) Red List of Threatened Animals." A secondary purpose is to present a comprehensive list of references to allow access to more detailed information on the species listed. From a misleading title, which gives the impression of a wider comprehensive coverage, to poor editing and a woefully inadequate list of references, this book (really a checklist) falls far short of meeting the needs of either the scientific community or administrators charged with monitoring the status of threatened species.

The book consists of three sections: introductory notes, species lists, and references. Taxonomy generally follows the most current source (e.g., Frost's *Amphibian Species of the World*), and is conservative in its treatment of controversial groups, such as tortoise genera. One taxonomic placement that I disagree with, however, is the inclusion of *Tomistoma* within the Crocodylidae rather than the Gavialidae (see Densmore 1983. *Evolutionary Biology* 16:397-465). The species lists include scientific and English common names, range (sometimes with accompanying reference number), CITES and Red Data Book status, major exploitation type, and reference number. The final section consists of the 549 numbered references corresponding to citations in the species list. Although otherwise alphabetical, nine references are tacked on the end of the bibliography and one (#545) is a repeat of #76.

For North American herpetologists, both errors and oddities in the species list abound. For instance, *Bufo nelsoni* is recorded from California where it does not occur; a common name of *Xerobates agassizii* is listed as "western gopher tortoise"; the only common name of *Gopherus polyphemus* is given as "Florida gopher tortoise"; one of the references for *G. polyphemus* (#210) actually refers to a survey of Gambian reptiles; St. Croix is included in the present distribution of *Ameiva polops* although the species has been extirpated from the island; the list states that *Charina bottae umbratica* is no longer recognized although the matter seems far from settled (see Stewart 1988. Proc. Conf. Calif. Herp., pp. 131-138). There also are distracting typographical errors, such as cocqui (p. 6), mountian (p. 10), and referernce (p. 24).

There are numerous errors or omissions in the reference section. Four references are listed by title only without an appropriate citation (#92, 308, 468, 499). One reference has a citation but no title (#549), while the citation and title are reversed in another reference (#493). In several instances, scientific names are not underlined (#59, 70), and typographical errors occur more frequently than, in my opinion, they should.

My main criticism, however, is that the book fails in one of its chief goals, i.e., to be a source of references for more comprehensive information on listed species. For instance, 136 species of lizards and 24 species of snakes are listed without any primary references whatsoever, although a few references are sometimes scattered under geographic distribution. If readers want more data on these species, where do they look? A second reference criticism is the reliance on unpublished reports, manuscripts, or even "in litt." citations (50 of 549). Indeed, some of the references with complete citations are extremely obscure (e.g., #155, *World Wildlife Fund Pakistan* 4(1):5-9), making them of dubious value as information sources. If the purpose of the book is to serve as a source for additional information (p. v), then the use of so many unpublished and obscure references is self-defeating.

A related problem is that checklists, rather than the primary literature, frequently are used as sources of information. For example, nearly every amphibian has Frost's *Amphibian Species of the World* as a reference. However, there are far more pertinent references for most species that give more information on biology and distribution. Most turtle references cite Iverson's *A Checklist with Distribution Maps of the Turtles of the World* rather than original or review works dealing with the particular species. The fact that the author did include very specific references in some instances highlights the uneven quality of the literature review.

Finally, specific literature citations are often outdated or not comprehensive. For example, Busack (1976, Biol. Conserv. 10: 309-319) is a better general reference for *Chioglossa lusitanica* than those listed; Mount (1975. *The Reptiles & Amphibians of Alabama*) gives more data on *Sternotherus depressus* than Iverson's checklist; Pritchard and Trebbau (1984. *The Turtles of Venezuela*) is mentioned only rarely in accounts of South American turtles. Many other examples are available. Indeed, Groombridge cites himself as author of the 1982 Red Data Book account on *Sternotherus depressus* when Robert Mount provided the account. And certainly, Fritts et al. (1982. J. Herpetol. 16:39-52) is more appropriate than having no reference at all for *Coleonyx switaki*!

Conservation biologists and resource managers do not need checklists containing spotty, incomplete information; they simply are of little or no value. Rather, detailed accounts, such as those in Groombridge's 1982 Red Data Book (*The IUCN Amphibia-Reptilia Red Data Book, Vol. 1*) are vitally necessary. This checklist offers little information on the species in question, appears hastily put together, and is excessive in price. Resource managers in the United Kingdom and researchers elsewhere should save their money and await the next volumes in the Red Data Book series.

Wildlife Management: Crocodiles and Alligators, edited by Grahame J.W. Webb, S. Charlie Manolis and Peter J. Whitehead. 1987. viii + 552 pp. + 10 color plates. Surrey Beatty & Sons Pty. Limited, 43 Rickard Road, Chipping Norton, New South Wales 2170, Australia.

In January, 1985, a "Technical Conference on Crocodile Conservation and Management" was convened in Darwin, Northern Territory of Australia, under the sponsorship of the Conservation Commission of the Northern Territory. This book includes the papers presented at that conference plus additional papers submitted *in absentia*. It includes 51 chapters broadly grouped into 10 sections. For Surrey Beatty & Sons Pty. Limited, this is yet another in their quality series of specialist conference proceedings. The publisher and editors are to be commended for a truly outstanding volume. Together, they have produced a text that is both handsomely crafted and remarkably free of production errors.

Part 1, "World Crocodilians," opens with a brief recount of the evolutionary history of the order Crocodilia. This is followed by a review of the distribution and status of modern crocodilians. Although this serves as a convenient checklist with distribution maps for each of the species, its utility is compromised by two shortcomings. First, the treatment of subspecies is inconsistent, subspecies being considered only within the *Caiman crocodilus* complex. Treatment of only species level taxa could certainly have been justified, but the selective exclusion of subspecies seems arbitrary. More importantly, this chapter is almost completely without literature citation. This is especially unfortunate in the discussion of the taxonomic confusion surrounding the *Caiman crocodilus* complex. Such statements as the following should not have been included without proper citation.

> 1) ". . .a major field authority on South American crocodilians proposed. . .", 2) "It has been proposed that this name should only be applied to. . ., while populations from. . .are distinct at the subspecific level and should be named *C. c. chiapasius*." and 3) "Two new subspecies. . .have recently been described and accepted in a major checklist. . ., yet these taxa are regarded as totally without foundation by others more familiar with the field situation."

Part II opens with a brief chapter on the World Conservation Strategy and CITES, which is then followed by 10 chapters detailing the history of management programs in the United States (Louisiana; Florida), Zimbabwe, India, Papua New Guinea, Venezuela,

and Australia (Northern Territory; Western Australia; Queensland). This section provides a valuable, historical overview of crocodilian management programs (both recovery and harvest) which have worked and those which have failed in various parts of the world. Part III, "Crocodile Management and Indigenous People," includes only two brief chapters, but they are a refreshing addition and emphasize the complex logistical and social issues which must be recognized if management programs are to be successfully implemented in cultures with very different economic perspectives or in which crocodilians are viewed as sacred.

The six chapters of Part IV provide an introduction to survey methods, techniques for gathering life history data, and population modeling. Part V includes two chapters focusing on the need for public education and providing approaches for cultivating public support for the goals of crocodilian management programs. Part VI includes four chapters covering techniques of capture, immobilization and anesthesia of crocodilians. Chapters 26 and 27, especially, are must reading for individuals who might have occasion to chemically immobilize crocodilians or to handle very large ones. Very large crocodilians may die from lethal acidosis resulting from prolonged struggling against manual capture (Chapter 26), and types of chemical immobilization effective on one species may prove ineffective on another. For example, ketamine hydrochloride, which is effective when used on *Alligator mississippiensis*, has proven lethal to *Crocodylus niloticus* (Chapter 27). The risks associated with handling and the possibility of interspecific differences in pharmacological response should always be kept in mind when working with rare species or valuable captives.

The three chapters of Part VII concern crocodilian behavior and thermoregulation, with a particular emphasis on management implications. The seven chapters of Part VIII discuss crocodilian farming and ranching operations in Zimbabwe, Thailand, Australia, and Israel, farming and ranching research in Louisiana and Florida, and diseases and disease control on crocodile farms. The four chapters of Part IX cover aspects of skinning; curing, storage, and marketing of hides; and identification of species from which skins or products have been derived. Part X includes ten chapters covering hormonal control of reproduction; chemistry, respiration, and water relations of eggs; embryology; and the effects of incubation temperature on sex determination, embryonic development rate, and post-hatching growth rate.

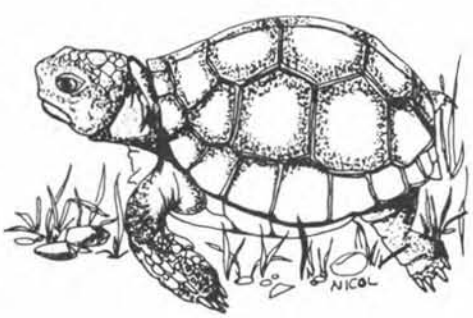
Given the size of the volume and the participation of 51 contributors, it is not surprising that there are occasional inconsistencies. For example, in Chapter 2 and on Plate 1 we are told that there are 22 species of living crocodilians, yet later (Chapter 28:289) we learn that "Nearly all of the 21 species of crocodilians have bred in captivity..." I at first thought that this discrepancy merely reflected the author's differing view regarding the specific distinctness of *C. mindorensis*, but elsewhere in the same chapter (p. 283) he makes reference to *C. mindorensis*. Other inconsistencies may be more apparent than real. In Chapter 43 it is indicated, based on tests with *C. johnstoni* eggs, that rotation of eggs is lethal if it occurs between days 2-13 post-laying, whereas Chapter 32, based on collection of *A. mississippiensis* eggs, suggests the period of sensitivity to be 7-16 days post-laying, with little mortality associated with egg movement up to day 7. This apparent inconsistency may represent real differences between the species investigated or simply differences between the effects of collection and those of actual rotation of eggs; the question is of real significance to management programs involving the collection of eggs for artificial incubation.

Also, in chapters dealing with crocodilians overall, there is an occasional tendency to overgeneralize from data on a few well known species. On page 278, for example, it is stated that "Crocodilians gape by opening their mouth for long periods, and this behavior may function to cool the head during basking." Although this behavior is common in most Crocodylinae and Gavialinae, it is seen much less commonly in the Alligatorinae, and its occurrence in *Paleosuchus*, for example, is doubtful.

One caption accompanying Plate 6 states that "The 'mouth-open' posture is partly a territorial display, but it also allows evaporative cooling across the palate, which effects (*sic*) the rate of heating of the head." Although the thermoregulatory function of open mouth gaping has often been cited, it is undocumented. The reference in the previous paragraph and another in Chapter 30 (p. 302) more conservatively suggest that gaping "may function...to alter heat exchange in the head versus the body," but it is noted on page 278 that gaping also occurs in the rain and at night. In this regard, the photograph on page 260 of a crocodile immobilized with gallamine triethiodide, a neuromuscular blocker, may be significant. This specimen is exhibiting a fairly typical mouth-open posture as a consequence of drug induced relaxation of the jaw musculature. In some cases, at least, gaping may indicate nothing more significant than relaxation.

Nonetheless, the shortcomings of this book are few and minor compared to its considerable value as a reference work on crocodilian biology and management. It belongs on the bookshelf of anyone with a serious interest in crocodilians and should be required reading for those who yearn for times past, when crocodilian management was concerned almost exclusively with recovery efforts.

PAUL E. MOLER
Florida Game & Fresh water Fish Commission
4005 South Main Street
Gainesville, FL 32601, USA



The Isle of Sea Lizards, by Angus Bellairs. 1989. The Durrell Institute of Conservation and Ecology, Canterbury. 299 pp. £5 ($8.15).

Novels by herpetologists or about herpetology are uncommon, and good ones are rarer yet. This book is the exception—an entertaining story with a herpetological theme that a herpetologist can read without wincing at the liberties being taken with the subject he knows. The basic plot is a familiar one—the remote island that serves as refugium for presumably extinct creatures, mosasaurs in this case, and inhabited by a relictual human population—descendents of mutineers from a mythical 18th century British sloop-of-war supplemented much later by the crew of a German submarine. Action shifts between a British university where a herpetologist and museum curator is engaged in a power struggle with a particularly odious American neurobiologist and the island where a liberal feminist government is confronted by a budding neo-Nazi movement that also threatens the mosasaurs. Interspersed through the book are numerous delightful digressions on topics as diverse as the history of the first mosasaur fossils, the last days of the Third Reich, and the raunchy "Hell-fire Club" of Victorian England.

Needless to say, the herpetology is first rate. In the hands of a master of reptilian functional anatomy, the mosasaurs are more believeable than some of the human characters. A colorful snake, evidently an undescribed Bolyerine, reposes on the bare breast of a Polynesian beauty and rates more descriptive prose than the lady. There is a glaring (and deliberate) misuse of the scientific name of a venomous snake—most readers will find it. At the novel's end, the mosasaurs have been formally described and registered for inclusion in the *Red Data Book*. Their island is safe, but one senses cruise ships just beyond the horizon. The herpetologist hero retains his museum and makes the Queen's Honours List.

Many herpetologists will see something of themselves or someone they have known. The story doesn't require too much suspension of disbelief particularly when you realize that *Varanus komodoensis* and *Latimeria* are discoveries of this century. Whether viewed as a tale of science fiction or adventure or a bit of both, this is good reading.

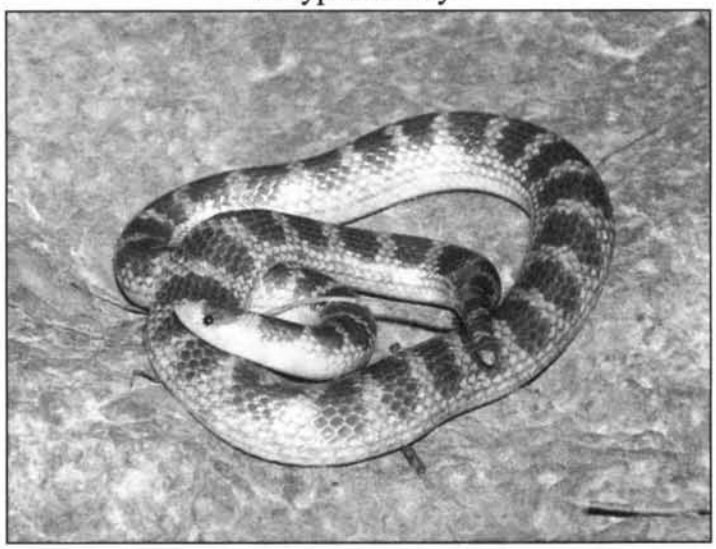
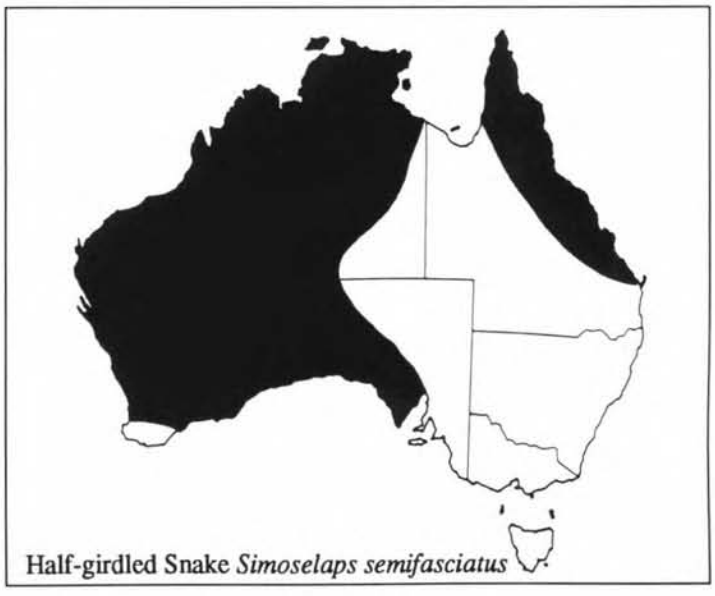
AUSTRALIAN REPTILES AND FROGS

The authoritative guide to more than 200 species



Australian Reptiles and Frogs
Raymond T. Hoser

This book results from the author's 20-year involvement with Australian reptiles and frogs. It provides detailed descriptions and 600 color photos of over 200 species of Australian reptiles and frogs.



In the largest collection of reptile and frog photographs ever published are pictures of reptiles never before photographed. Some world firsts in this book include photos of copulating snakes of different species, snakes feeding and copulating simultaneously, and breeding of the recently rediscovered Ant-Hill Python Bothrochilus perthensis. In addition to the stunning photographs, the book contains valuable information on Australia's herpetofauna, including origins, natural history, classification, identification, habitats, keeping, breeding, photography and conservation.

Half-girdled Snake *Simoselaps semifasciatus*

About the author.

Raymond Hoser has a world reputation for his activities in the field of reptiles. At St. Ives and Redfern, New South Wales, he managed one of the premier reptile captive-breeding facilities in Australia. After a clash with the Parks and Wildlife Service in New South Wales he left his position in 1985, but has continued his herpetological interests and deep interest in conservation. The author is also a highly skilled photographer, as evidenced by the color plates in the book.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to rtteview herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations and photographs. Manuscripts submitted must be typed, double spaced, on 8.5X11 inch paper, and should be sent in duplicate. We encourege submissions on Macintosh disks, though we can also work with TEXT (ASCII) files submitted on IBM and compatible floppies. **Herpetological Review** is composed on a Macintosh SE using Microsoft Word, which accepts files from several other word processor applications. Format your documents full-page width; we will fit to **HR** format. Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8X10 inches black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. Herpetological Review will accept commercial advertising. Rates and copy information are available from the advertising manager. Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats. Contact the Managing Editors for details. All ads are accepted at the Editor's discretion.

Society For The Study Of Amphibians And Reptiles

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (4 issues annually), **Herpetological Review** (4 issues annually), and occasional issues of **Facsimile Reprints In Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1989

Student member.....$25.00*	Sustaining member.....$50.00*
Regular member.....$35.00*	Contributing member.....$75.00*
Institutional subscription.$60.00*	Life member..(see below)...$600.00*

***Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00.

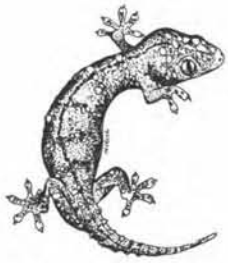
Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, draft on a US bank, or by Mastercard or Visa (include account number and expiration date of credit card). Life memberships may be paid in 3 consecutive payments

Subscriptions to Herpetological Review only are available for $12.00 annually.

Subscriptions outside of the US require a surcharge of $8.00 for air delivery if airmail is desired. Subscribers to HR only are not members of the Society.

Catalogue of American Amphibians and Reptiles: subscription $15 annually ($3.00 air delivery surcharge if airmail is desired.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).



Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc., RFD 6 Box 1, Lawrence, KS 66046. Steve Meseraull, Printer. SSAR BUSINESS

SSAR GRANTS-IN-HERPETOLOGY

Proposals are now being accepted for the 1990 SSAR Grants-in-Herpetology Program. This program is designed to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. In keeping with the Society's goal of encouraging participation of the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR, with the exception of those applying in the REGIONAL HERPETOLOGICAL SOCIETY category. Applicants are limited to submission of one proposal in one category per year. If proposals in any of the categories are not forthcoming, or judged not be of sufficient quality, the funds in those categories may be transferred to other categories. Grant proposals will be considered in the following categories:

1. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address educational projects, speaker's fees, regional research, defrayment of one-time-only costs, or other purposes that would strengthen regional societies. Proposals may be submitted by regional herpetological societies or by individual members and must be accompanied by a letter of support from the current president of the regional society.

2. HERPETOLOGICAL RESEARCH OR EDUCATION IN ZOOS. Proposals may address any herpetological endeavor conducted in zoos, such as improvement of displays, husbandry, or behavioral research. A lettter from the director or herpetological curator of the sponsoring zoo must accompany the proposal.

3. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species. Proposals must be from individuals only and must be accompanied by a letter of support from another member of the SSAR.

4. FIELD WORK. Proposals may address support for travel to ecological study sites or for survey collections. Proposals normally submitted in the CONSERVATION or GRADUATE STUDENT RESEARCH categories, but for travel (or field station) support, should be submitted here. Proposals for survey collecting are appropriate for this category. Proposals must be from individuals only and accompanied by a letter of support from another member of the SSAR.

5. GRADUATE STUDENT RESEARCH IN HERPETOLOGY. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only. Applications must be accompanied by a letter of support from the student's major advisor or committee chairperson.

Each proposal must include the following: (A) BACKGROUND AND OBJECTIVES of the proposed project. (B) METHODS of carrying out the project. (C) BUDGET, which should not exceed $300. (D) BRIEF RESUME of the applicant or project coordinator. (E) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages, excluding resume and budget.

Applicants must designate to which of the five categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted in duplicate and postmarked no later than 31 January 1990. Failure to meet the guidelines may result in elimination of a proposal from consideration. The awards will be announced by 1 April 1990. Successful applicants will be expected to submit to the SSAR a written report of the result of this support within a reasonable amount of time after the project year is completed. They are also encouraged to submit the results of research projects for publication in the **Journal of Herpetology** or **Herpetological Review** or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to:

DARREL FROST, CHAIR
SSAR Grants-in-Herpetology Committee
Museum of Natural History
University of Kansas
Lawrence, Kansas 66045, USA
(913 864-3439)

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number of awards in this program. Your tax-deductible contribution to this program will benefit directly meritorious research and education in herpetology. Contact the President of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program. ●

REPORT OF THE GRANTS IN HERPETOLOGY COMMITTEE 1989

Committee: Dale Belcher, Arthur Echternacht, Thomas Fritts, Darrel Frost (Chair), Michael Plummer, Eric Rundquist.

In 1989 the Grants in Herpetology Committee reviewed proposals in four categories: Zoo Research (2), Graduate Student Research (17), Conservation (5), and Regional Societies (5). Of these, one in each of the four categories was awarded a grant of $350.

Zoo Research: "Competitive ability of sympatric tadpoles, *Bufo houstonensis* and *Bufo valliceps*." Recipient: Steven B. Reichling, Department of Herpetology, Memphis Zoo and Aquarium, Memphis.

Graduate Student Research: "Evolution of parental care: a multidisciplinary approach in some dendrobatid frogs." Recipient: Ellen M. Smith, Department of Zoology, University of Washington, Seattle.

Conservation: "Studies in the bacteriology of the red-eared slider turtle, *Trachemys scripta*, under ware-housed and wild conditions." Recipient: Barbara Bonner, Department of Microbiology, University of Massachusetts, Amherst.

Regional Societies: "Educational program on the venomous snakes of North Carolina." Recipient: North Carolina Herpetological Society. Project Director: Ann B. Somers, Greensboro, North Carolina. ●

NEWSNOTES

INFORMATION REQUEST

Beginning in 1977, the Vertebrate Pests Committee of the Standing Committee of Agriculture (Australia) has been working to develop guidelines for uniform legislation by all Australian States and Territories, to provide adequate control over the introduction, movement and keeping of vertebrate species not indigenous to Australia. The proposed legislation's objective is to control animal species which are actually or potentially a threat to agriculture, the natural environment or public safety.

As part of these endeavours, lists of species in Australia have been developed and efforts are now being directed towards a rational process of risk assessment. To assist in this process and provide important background data for the reclassification of reptile and amphibian species proposed for importation into Australia, information is requested on the establishment, anywhere in the world, of any species of reptile or amphibian in the wild outside its natural range.

In particular, details are sought on the species concerned, where and when it/they became established, and how the establishment arose (escape, release, etc.). Particulars on the threat posed and steps taken to minimize or halt the damage, would also be of great assistance. Copies of any published accounts of this/these establishments would be appreciated.

Please send to: Chris B. Banks, Curator of Reptiles, Royal Melbourne Zoo, P.O. Box 74, Parkville; Victoria 3052, AUSTRALIA. ●

TOLEDO ZOO SEEKS CURATOR OF REPTILES

The Toledo Zoo, Toledo, Ohio, is seeking to fill the position of Curator of Reptiles. Preference will be given to applicants holding a bachelor's degree (or higher) in biology, zoology, or related field, with an emphasis in herpetology. The Curator will be responsible for acquisition, breeding and maintenance of the collection and supervision of the keeper staff. Previous curatorial experience preferred. Salary range is $24,000-$28,000 with excellent benefits.

Send letter and resume to: Libby Westerhausen, Personnel Coordinator, the Toledo Zoo, 2700 Broadway, Toledo, OH 43609, USA. ●

NEW OUTLET FOR HERPETOLOGICAL PUBLICATIONS IN THE NORTHWEST

In 1988, the membership of the Pacific Northwest Bird and Mammal Society expanded the taxonomic scope of its activities to include amphibians and reptiles. The name of the Society was changed to the Society for Northwestern Vertebrate Biology and the journal, which had been called *The Murrelet* since its inception in 1920, was renamed the *Northwestern Naturalist*.

The journal is now accepting original contributions dealing with the biology of birds, mammals, amphibians, and reptiles in northwestern North America. This is defined as Alaska, Yukon, District of Mackenzie, British Columbia, Alberta, Saskatchewan, Washington, Oregon, Idaho, Utah, Montana, Wyoming and Colorado west of the Great Plains, and Nevada and California north of the Mohave Desert. As a regional journal, the *Northwestern Naturalist* will also publish distributional records of interest, including first and second records of a species for a State, Province, or large biogeographical region.

Address all manuscripts or requests for additional information to:

Frederick F. Gilbert
Editor, *Northwestern Naturalist*
Department of Natural Resource Sciences
Washington State University
Pullman, WA 99164-6410, USA

Submitted by Keith B. Aubry, Associate Editor in Herpetology; U.S. Forest Service, Pacific Northwest Research Station, 3625 93rd Ave. SW, Olympia, WA 98502, USA ●

JOHN GIBBONS TRUST FUND

Dr. John R. H. Gibbons, his wife Lily, and their two children were drowned in a tragic accident near the island of Lakeba, on 15 November 1986. At the time of his death, Dr Gibbons was a Lecturer in Biology at the University of the South Pacific. He had served with the University for eight years.

In memory of Dr. Gibbons' contributions to teaching and research in biology, and to his pioneering efforts in the conservation of local wildlife, the Council of the University of the South Pacific has authorized the institution of a Trust Fund to finance an academic prize or scholarship. The fund will receive private donations and the income arising from investment will be used to finance the prize or scholarship.

Individuals who were acquainted with John, his work, or his family are invited to contribute to this fund. Checks or money orders should be made out to The John Gibbons Trust Fund and sent to: Senior Accountant (Special Affairs), Bursar's Office, University of the South Pacific, P.O. Box 1168, Suva, Fiji ●

MEETINGS

PITVIPER SYMPOSIUM

A Symposium on the Biology of Pitvipers, celebrating the 50th Anniversary of the founding of the Texas Herpetological Society, will be held 17-19 November 1989 at the University of Texas at Arlington. The program will consist of about 18 invited presentations, poster sessions, slide shows, tour of the Dallas and Fort Worth Zoos, and a social, banquet, and auction. Program information and registration material may be obtained from: Jonathan A. Campbell, Department of Biology, UTA Box 19498, Arlington, TX 76019, USA ●

14th IHS

The 14th International Herpetological Symposium on Captive Propagation and Husbandry will be held 20-23 June 1990 in the Dallas-Fort Worth area of Texas. In addition to the paper sessions, there will be several workshops, visits to the renowned Dallas and Fort Worth Zoos, barbecues, and other activities.

A Call for Papers will be issued in December, but individuals wishing to present papers or organize workshops are invited to submit their proposed titles to the symposium organizers at this time.

Individuals who attended IHS meetings over the past two years are on the mailing list and will receive registration material in March 1990. Those who have never attended an IHS meeting, or who have not done so in the last two years and who wish to be added to the mailing list, should contact the symposium coordinator.

Inquiries regarding IHS meetings should be directed to: Dr. Michael J. Uricheck, Symposium Coordinator, Department of Chemistry, Western Connecticut State University, Danbury, CT 06810, USA, (203) - 797-4232, 754-6839 ●

REGIONAL SOCIETIES

CFHS 1989-90 Scholarship Recipient Selected

Each year the Central Florida Herpetological Society awards a full scholarship to someone who has been accepted into the Biological Parks Program at Santa Fe Community College in Gainesville, Florida. Upon graduation from this program, students receive an Associate's Degree in Biological Parks Management and are qualified to work at zoos or other attractions that require exotic animal care.

In the selection of a scholarship recipient, it is important that the student have an interest & background in herpetology. However, students in the Biological Parks Program receive training in the care of a wide variety of animals. We are pleased to announce the 1989-90 scholarship recipient is Charles Jenkins from Eustis, Florida.

Last year's scholarship recipient, Nicole Haff, has graduated from Santa Fe Community College. She is currently employed at Ophiological Services in Gainesville, Florida. ●

Jay Veltkamp, 1989 President of the Central Florida Herpetological Society and Charles Jenkins, this year's scholarship recipient.

SPRING ESHL MEETING

The spring meeting of the Eastern Seaboard Herpetological League will be held on Saturday, 17 March 1990 in Greenville, North Carolina. The meeting will be hosted by the North Carolina Herpetological Society. The program for the meeting, along with information on travel and accommodations, will be mailed to all constituent societies of ESHL by the end of the year. Herpetologists who are not members of a regional herpetological society may obtain information about this meeting by contacting: Dr. Michael J. Uricheck, Department of Chemistry, Western Connecticut State University, Danbury, CT 06810, USA, (203)-797-4232, 754-6839 ●

LEGISLATIVE ALERT

MICHIGAN PROTECTS ITS REPTILES AND AMPHIBIANS

Michigan has been, regrettably, one of the last states to recognize the ecological and economic values of reptiles and amphibians, and the need to conserve and manage this resource. Strict laws have existed for many years to manage and protect fish, birds, and mammals, while amphibians and reptiles have been practically ignored. The Endangered Species Act of 1974 does protect a few species that are either greatly diminished in numbers or are peripheral species in Michigan. However, habitat loss and direct exploitation have reduced many other species which do not yet fit the specific criteria for listing as "endangered" or "threatened." Now, with the passage of Public Act 373 of 1988, the State will have the ability to better regulate the exploitation of reptiles and amphibians. The act may also, indirectly, encourage better public education concerning these animals.

PA 373 amends an earlier act (PA 165 of 1929) and basically declares all fish, reptiles, amphibians, mollusks, and crustaceans to be the property of the State of Michigan, authorizes the regulation of "taking, possession, transportation, size, and sale" of these animals, and provides for licensing and penalties for violations of the act. It states that the animals concerned may only be taken "in a manner and during those times prescribed by the director of the Department of Natural Resources." It requires persons taking or catching turtles or frogs to have a fishing license, and further requires persons taking, trapping, or catching reptiles and amphibians for commercial purposes (e.g. for sale or profit) to purchase an annual license for $150.

The new regulations were prepared by the Fisheries Division, with advice and input from D.N.R. personnel and other knowledgable and interested persons (including professional herpetologists, private individuals, hobbyists, and representatives of Michigan United Conservation Clubs and the Michigan Society of Herpetologists). Some of the more important points contained in the director's order are summarized below:

- Certain rare, declining, or vulnerable species are now protected by law and *cannot* be taken from the wild. These include the Eastern box turtle (*Terrapene c. carolina*), the wood turtle (*Clemmys insculpta*), the spotted turtle (*C. guttata*), the black rat snake (*Elaphe o. obsoleta*), and the cricket frog (*Acris c. blanchardi*). These are all listed as "special concern" species under the Endangered Species Act. Of course, any species listed as officially "endangered" or "threatened" is fully protected (check with the DNR Wildlife Division for an updated list).
- Turtles and other amphibians or reptiles may not be taken with firearms. (Turtle "plinking," a serious problem in some areas, is now illegal.) The order states several methods which may be used, including traps, hook and lines, hand nets, and by hand. Turtle traps must be constructed of mesh at least 1 inch wide, must be set so that trapped animals can breathe, and must bear the user's name, address, and license number.
- Reptiles and amphibians must be possessed and transported in the field in a manner that allows clear identification of species and size. Any such animals taken that are protected, under legal size, or out of season, must be immediately released to the wild.
- Snapping and softshell turtles can only be taken from 1 July to 30 September in the Lower Peninsula, and from 15 July to 30 September in the Upper Peninsula (protecting them during winter hibernation and when breeding or nesting). These species must have a carapace length of 12 inches to be kept. Snappers have a daily and possession limit of 10, except that holders of a commercial reptile and amphibian license may possess up to 30. Softshells have a daily limit of 2, and a possession limit of 6.
- All other reptiles (those not otherwise protected) have a daily catch limit of 2 and a possession limit of 6, except that holders of a commercial license may take up to 25 Eastern garter snakes daily, and may possess up to 50. Reptiles taken from the wild cannot be bought or sold, except that a holder of a *commercial* license can buy or sell animals legally taken and possessed in accordance with the order.
- Reptile eggs may not be disturbed or removed from the wild.
- Frogs and toads can only be taken from the last Saturday in May to 15 November. (These dates were determined by previous legislation.) Salamanders may be taken from 15 March to 15 November. The daily and possession limit for amphibians is 12. A person holding a *commercial* reptile and amphibian license can take or possess up to 200 frogs. A holder of a commercial license may take up to 500 salamanders daily, with a possession limit of 1000. Only the following species of amphibians may be taken for commercial purposes: Leopard, pickerel, green, and bull frogs, and tiger, spotted, and blue-spotted salamanders, mudpuppies, and newts.

The regulations summarized above took effect in spring, 1989.

MINNESOTA REMOVES RATTLESNAKE BOUNTY

The Minnesota Legislature voted to eliminate the payment of bounties on rattlesnakes by county or township governments. The governor signed the bill on 9 May 1989 and it took effect on 1 August 1989. The bounty had been in the state statutes for over 50 years. There were four counties in the southeast corner of the state still paying bounties.

The legislation was introduced and promoted by the Minnesota Herpetological Society with assistance from the Nongame Wildlife Program of the Minnesota Department of Natural Resources. ●

FEATURES

ANALYSIS OF A *Python anchietae* FAECAL SAMPLE

Only a single report on the natural diet of the Angolan dwarf python, *Python anchietae* appears in the literature (Steyn and Els 1963). Additional information on the feeding habits of this species is therefore of considerable value.

Python anchietae is a small, rare python associated with the hills and mountains of the Namibian and southern Angolan escarpment. The southern limit of its range is 22° S. The only available record on the natural diet of this species (Steyn and Els 1963) reports recovery of the head of a gerbil, *Tatera schinzi* (= *T. leucogaster*, the bushveld gerbil; see Meester et al. 1986) from the stomach of a dead specimen.

Steyn and Els (1963) also reported feeding a captive specimen on the sparrow, *Passer jogoensis motitensis*. Since no sparrow with this species name has been described, the author (or publisher) may have misspelled *iagoensis*. Also the subspecies, *motitensis* does not appear to have been formally described. Howard and Moore (1984) give the distribution of *Passer iagoensis* as the Cape Verde islands, so it would appear that the referred-to species is most probably the great sparrow, *P. motitensis benguellensis* (Howard and Moore 1984; Maclean 1985). The main diet of specimens at the Transvaal Snake Park, where a captive breeding programme is in operation, is the multimammate mouse, *Mastomys natalensis* which is readily taken (Morgan, pers comm.).

On 25 June 1985, a female *Python anchietae* (snout-vent length = 915 mm; tail length 106 mm) was donated to the Transvaal Snake Park after being collected in southern Angola and confiscated by the Directorate of Nature Conservation. Shortly after its arrival at the Park the specimen defecated and the sample was stored in 70% alcohol until analysis in November 1988.

Analysis of the faeces at X16 revealed the following:

Feathers: The bulk of the sample consisted of feather remains which were very broken up by digestive action. As no reference collection for this type of material was known to the author, detailed chemical and electron microscopic analysis were not carried out. Day (1966) considered the nodes on the downy barbules of covert feathers to be diagnostic to order level. An examination of covert feathers from orders such as Galliformes, Columbiformes and Passeriformes showed that there were distinct differences in the nodes and the pigmentation at the nodes of the barbules. Microscopic comparisons with the feather remains in the faecal sample indicated that these remains were Passeriformes and of the genus *Passer* (Ploceidae).

Hair: Identification was based on the negative cuticular scale patterns of hairs which were produced on gelatin-coated slides after Day (1966), Brunner and Coman (1974), Douglas (1985 and 1988 unpublished) and

Keogh (1985). Final identification was based on a negative cuticular scale pattern reference collection, compiled from hairs in the National Museum Mammalogy Department study skin collection. Work being done on other species by the author has shown that a large amount of dietary information may be lost in studies of this type by not identifying the hair portion and that up to 70% of this information may be lost, particularly from intestinal and stomach remains. Examination of the sample revealed only 11 individual pieces of hair. Owing to the fact that the majority of the hairs were only pieces of hair or not guard hairs (on which this type of identification is based), only one positive identification was possible, namely that of an elephant shrew, Macroscelididae. It was not possible to be more specific because: (a) R. Parker (1985, pers. comm.) found that while working on Macroscelididae guard hairs, there were no defining morphological characters which enabled identification to below family level, and (b) Distribution records for Macroscelididae in southern Angola are very incomplete.

Other recognizable items: Twelve teeth of the python were found in the sample and were either swallowed during tooth replacement or were lodged in the prey items when these were caught or swallowed.

A portion of chitinous insect remains was also present, but these were regarded as secondary items, possibly from the Macroscelididae specimen.

Fairly large amounts of very fine quartz gravel were evident and were most probably ingested while swallowing prey or were present in the digestive tracts of prey items.

The results of this analysis indicate that birds and small mammals are eaten by *Python anchietae* in the wild. The feather, mammal hair and other limited feeding data available, would also imply that *Python anchietae* is an opportunistic feeder.

ACKNOWLEDGMENTS

I would like to thank R. Boycott, formerly of Transvaal Snake Park, for supplying the sample; D. Morgan, present Curator of Transvaal Snake Park, for information relating to the specimen; and R. Parker, formerly of the Mammal Research Institute, University of Pretoria, for his valuable information on Macroscelididae hair identification. I would also like to thank S. Louw and M. Bates of the National Museum of commenting on the manuscript.

HERPETOLOGY AT THE SAVANNAH RIVER ECOLOGY LABORATORY

Over 200 herpetological research publications have been generated by the resident staff, students, and affiliates of the Savannah River Ecology Laboratory (SREL). SREL is operated by the University of Georgia under contract with the U.S. Department of Energy (DOE). Although well-equipped for controlled organismal and population research in laboratory and outdoor seminatural enclosures, SREL is particularly conducive to field research. It is located on 483 km² of protected, DOE-owned land in South Carolina called the Savannah River Site (SRS). The SRS is bordered on the southwest by the Savannah River and encompasses parts of Aiken, Barnwell, and Allendale Counties, about 40 km SE of Augusta, Georgia. Although the SRS's prime function is the production of radionuclides, the site is designated as a National Environmental Research Park. Hence, long-term research can be done on much of the SRS without the threat of habitat destruction or public interference, particularly at the exclusive SREL research areas. More than 8100 ha have been declared by DOE as research set-aside habitats that are protected from industrial development and forestry programs.

The SRS is within the sandhills region of the Upper Coastal Plain, about 32 km downslope from the Piedmont and 32 km upslope from the Lower Coastal Plain. Possiblities for field research are enhanced by the diversity of terrestrial habitats on the SRS. Many old fields, abandoned since 1951, are now either pine plantations (58000 ha) or turkey oak-long leaf pine associations (2000 ha). Terrestrial communities also include scattered stands of upland hardwoods (1000 ha), more extensive lowland hardwood forests (8000 ha), and, nearer the Savannah River, cypress-black gum forests (2000 ha).

Some of the best herpetological research opportunities on the SRS have proven to be in and along the many aquatic environments on the SRS (see Representative Publications). Notable are the numerous streams and more than 190 Carolina bays, the natural, lentic freshwater wetlands of the region (average size is 2.7 ha, range 0.1-50 ha). Some Carolina bays retain water almost permanently, whereas most are ephemeral. Swamps (3000 ha) and floodplains along the Savannah River, farm ponds, and four reservoirs are also available for research.

The diversity of habitats, mild climate, and extensive herpetological field research for more than 20 years are the primary reasons for the recorded capture and documentation of more than one million individuals and 100 species of amphibians and reptiles on the SRS. The plethora of research possibilities presented by so many species is demonstrated by the diversity of research of the two herpetologists in permanent residence at SREL, J. Whitfield Gibbons and Justin D. Congdon, and the large number of post docs, technicians, graduate students, visiting faculty, and undergraduates.

Dr. J. Whitfield Gibbons (representative publications 1, 2, and 3) has been investigating questions concerned with the life history and evolutionary ecology of freshwater turtles. The studies are formulated in a manner to apply basic biological research findings to local or natural environmental problems that address contract obligations of funding agencies and organizations. Some of the major habitats in this program have been the Carolina bays known as Ellenton Bay, Flamingo Bay, and Lost Lake, and the reservoir known as Par Pond, all on the SRS. Dr. Gibbons has also conducted long term research at Sherriffs's Marsh in southwestern Michigan, in association with Michigan State's Kellogg Biological Station. Recent accomplishments include the completion of *Life History and Ecology of the Slider Turtle* (Smithsonian Institution Press, in press). The 10000 marked turtles on the SRS are the focus for continued field observations of and experiments on turtles. Dr. Gibbons attributes the success of the program to the involvement of numerous colleagues, especially Judy Greene. Othes recently involved directly in the turtle studies are Tony Mills, Marie Fulmer, Jeff Lovich, Steve Morreale, Tim Owens, and Sarah Collie.

Dr. Justin Congdon, also a SREL staff herpetologist, is examining parental investment and developmental energetics of embryos of turtles, snakes, lizards, and alligators on the SRS. His results indicate that at least half the lipids present in the egg are available to the offspring after hatching, hence these lipids can be considered a form of parental care (publication number 4). Dr. Congdon also uses a multi-year, repeated-capture study of turtles on the George Reserve in Michigan to investigate life history evolution of long-lived organisms (numbers 5 and 6).

Trip Lamb, a post-doc with Whit Gibbons, has examined the effect of hybridization of the genetic architecture of anurans (7) and uses mitochondrial DNA analysis to address zoogeographic variation in the turtle genera *Xerobates* (8), *Malaclemys*, and *Graptemys*. He also uses flow cytometry to study genetic damage of nuclear DNA in turtles (*Trachemys scripta*) inhabiting radioactive seepage basins on the SRS (9).

Roger Anderson (10), a post-doc with Justin Congdon, is working in the turkey oak-longleaf pine woodlands on the SRS, studying the daily patterns of thermoregulation, movement, prey capture and metabolism of

lizards which differ in food acquisition modes. In the lab, Dr. Anderson is using locomotory performance measures to investigate the adaptedness of lizard body form as it relates to food acquisition mode and predator evasion requirements.

Several graduate students are pursuing Ph.D. research at SREL. Robert "Bud" Fischer, technician with Justin Congdon and Ph.D. student at Clemson University, has been collaborating with Dr. Congdon on aspects of parental investment in reptiles and fish. Bud has also been working with several visiting faculty on numerous aspects of the physiology of alligators. Jeff Lovich (3, 11, & 12), University of Georgia Ph.D. candidate under Dr. Gibbons, is investigating sexual size dimorphism and sexual dichromatism in turtles, focusing on effects of sexual selection and natural selection on the evolution and maintenance of sexual size dimorphism in *Trachemys scripta* and *Malaclemys terrapin.* Joe Pechmann (13 and 14), technician with Dr. Gibbons, and Ph.D. candidate from Duke University, under the direction of Dr. Henry Wilbur (Duke University) and Dr. Gibbons, is developing terrestrial and aquatic field experiments on ambystomatid salamanders. He is using large-scale enclosures adjacent to two Carolina bays to analyze regulation of population sizes and community structure in larval and adult amphibians. David Scott (14, 15 & 16), a technician under Dr. Gibbons, and Ph.D. student at the University of Virginia, working with Dr. Gibbons and Dr. Ed Connor (University of Virginia), is also using large-scale enclosures for aquatic field experiments in two Carolina Bays. He wants to determine the effects of intraspecific and interspecific larval interactions on larval and adult traits in *Ambystoma opacum* and *A. talpoideum.* Thomas Hinton (16), Ph.D. candidate at Colorado State University under Dr. Ward Whicker and Dr. C. Richard Tracy, is working with Dr. John Pinder, a radioecologist at SREL. Tom uses radioactive tracers to examine the assimilation and retention of radium, strontium, and calcium in *Trachemys scripta* as influenced by age, sex, season, and stable calcium in the diet.

Three Masters students are currently working with SRS reptiles. Ray Lorraine (University of South Florida) studies the foraging ecology of *Seminatrix* at Ellenton Bay. Laura Brandt (Florida International University) is examining population structure and density of *Alligator mississippiensis* in Par Pond Reservoir. Dave Penick (SUNY, Buffalo) is examining daily field metabolism and thermal ecology of *Terrapene carolina* in bottomland hardwoods.

SREL also provides research opportunities to visiting herpetologists. Some receive a stipend and travel expenses through cooperative research programs between SREL and the Oak Ridge Associated Universities Program. No fewer than a dozen visiting faculty have been involved in herpetological research at SREL in the past two years.

One such visiting faculty is Ray Semlitsch (Memphis State University) who is continuing work on ecological and genetic consequences of paedomorphosis in *Ambystoma talpoideum* from the SRS (14, 17 & 18). Drs. Semlitsch and Gibbons have also completed a field guide to the reptiles and amphibians of the SRS, due for publication in 1989. Rich Siegel (Southeastern Louisiana State University) is also a visiting faculty who recently finished a post-doc under Whit Gibbons (19 & 20). He has been examining the life history and population ecology of aquatic and terrestrial snakes: *Nerodia taxispilota, Seminatrix pygaea,* and *Coluber constrictor.* He and Mary Jackson (Master's candidate at Memphis State University) have recently completed work on the effects of temperature on the locomotor ability of *Seminatrix.*

Dr. William Cooper (Auburn University at Montgomery) and Dr. Laurie Vitt (UCLA) have published 20 papers in the past five years from research performed as visiting faculty at SREL (see 21 and 22; Dr. Cooper has several more with Dr. William Garstka, University of Alabama) on various aspects of *Eumeces* biology such as reproduction, lipid cycling, diet, chemical communication, and sexual selection. Drs. Garstka and Cooper have been working with Jeff Lovich in examining the efficacy of using castrated and hormonally implanted *Trachemys scripta* for mate-choice experiments. Dr. Neil Ford (University of Texas, Tyler), in collaboration with Rich Siegel, has used laboratory experiments to study how foraging success affects the reproductive potential of *Thamnophis marcianus* and *Elaphe guttata* (19 and 20). Dr. Gordon Ultsch (University of Alabama) has recently completed work at SREL on aspects of the physiology of the respiratory and circulatory systems in musk turtles and box turtles (23).

Still more visiting faculty are collaborating with researchers at SREL. Dr. Nat Frazer (Mercer University) has worked with Dr. Gibbons during the last three years on age-dependent growth models in turtles. Dr. Jim Spotila (Drexel University) has been working closely with his student Dave Pennick on *Terrapene carolina,* and continues to be interested in temperature-dependent sex determination in reptiles. Dr. Robert Gatten (University of North Carolina) and Justin Congdon have recently completed a study of anaerobic metabolism in nesting *Chrysemys picta.* Dr. Gatten, Dr. Frank Mazzotti (University of Florida), Dr. Congdon, and Bud Fischer have been examining the anaerobic component of sustained and burst activity in *Alligator mississippiensis.* Dr. Mazzotti has also been working with Dr. Gatten, Bud Fischer and Dr. Congdon on parental investment in alligator embryos as affected by temperature. George McCoy (Benedict College) is collaborating with Bud Fischer and Dr. Congdon on the effects of temperature on the rates of metabolism and development of alligator embryos.

SREL has other attractions. Top quality undergraduates come to SREL from all over the United States under the auspices of the SREL/DOE Cooperative Research Program. Each student participates in research for 10-12 weeks. More than a dozen SREL publications in herpetology have been a consequence of undergraduate projects. Graduate students can also be supported through this program to conduct their research for up to three years. The invited seminar program at SREL brings in a total of about two dozen herpetological seminars each year. The SREL library has 135 journal titles and many books relevant to ecology; a rapid interlibrary loan arrangement with the main campus fills the need for other references. The 16 other faculty members at SREL (all ecologists, in such fields as plant ecology, biogeochemistry, ornithology, mammalogy, ichthyology, aquatic invertebrate ecology, and microbial ecology), their post-docs, graduate students, technicians, and colleagues also help create a bustling academic environment. There are many reasons, indeed, for the exemplary ecological research in herpetology at this dynamic institution.

INCONSISTENCIES, INACCURACIES, AND INADEQUACIES IN HERPETOLOGICAL METHODOLOGY AND TERMINOLOGY, WITH SUGGESTIONS FOR CONFORMITY

The responsibilities of scientists include being objective, finding truth, organizing to prevent chaos, and establishing accuracy and consistency. Communication is difficult enough; language may have several meanings for the same word, several spellings for the same pronunciation, several pronunciations for the same spelling, and so on. Herpetology has its own peculiar flaws, some of which form the subject matter of this report.

First, consider higher category nomenclature—it needs stabilization. For example, compare usage such as Caudata vs Urodela, Salientia vs Anura, Testudines vs Chelonia vs Testudinata, Sauria vs Lacertilia, all names of wide usage, but shamefully not subject to the restrictive rules that we apply to family group names via the International Code of Zoological Nomenclature. Very few authors cite authorities for the higher taxon names. These dualities are the subject of another manuscript that I have in preparation.

Where do we learn terminology and methodology? From our mentors? From textbooks? From literature? From our own researches? Regardless of how, the fact is that we often do things differently without defining our methods clearly, or we blindly follow something we have read without examining its accuracy. And we omit because we follow someone else's format. Below I provide examples with suggestions for correct usage or improvement.

OMISSIONS

Many papers fail to give maximum or minimum sizes for specimens: identification is often assisted when size range is known, and additionally our curiosities are sated. Many papers give only total length or body length (the latter especially in salamanders) and may not clearly state what the length figure represents, e.g. Rossman and Wallach (1987) merely say "length"; Vermersch and Kuntz (1986) say "body length" for *Leptotyphlops* but simply say "length" for others; Martof et al. (1980) give total length for anurans and carapace length for turtles, but only total length for other groups; Salthe (1973) and Anderson (1969) omit length entirely. Few articles give allometric growth data. In Salamanders, length ratios (e.g., tail to body) typically change from juvenile to adult; such changes are useful in systematics and help explain adaptive or ecological functions.

How often does an investigator give scale count data in relation to size or age of specimens? Dunn (1942) and Inger (1943) offered ideas on survival value of varietal characters. Abnormal ventral or subcaudal scale counts are more likely in juveniles, which may die off early and thus would have different count ranges or frequencies. I recommend that meristic data be presented for different size groups (or age groups) either as statements of range or, more ideally, as graphs for the count distribution of the different groups.

METHODOLOGY

Many workers, certainly amateurs, get their nomenclature and measurement methods from popular field guides or compendia texts. Are these reliable sources of methodology? Let's compare and make a determination. Conant (1975) shows snout-vent length in salamanders as being from tip of snout to distal end of vent. Stebbins (1985), in the

same guide series, does not define or show how S-V length is determined, but obscurely in the text he says snout-to-vent, which suggests proximal end of vent. The major text on salamanders (Bishop 1943) usually said total length and tail length, but on occasion would say length to posterior end of vent. Duellman and Trueb (1986), Porter (1972), and Goin, Goin, and Zug (1978) give no details on S-V length, thus a logical source of definition would seem to be Peters (1964). This latter reference states that the main use of the term S-V length is to the posterior end of the vent, occasionally to the anterior end. An unusual approach to the problem appears in Pfingsten and Downs (1989). They used "standard length" for data known to be based on snout to posterior angle of the vent, "snout-vent length" for measurements known to extend only to the anterior angle of the vent *and* for data gleaned from publications where authors did not specify their method of measuring body length. Obviously the latter interpretation does not provide readers of original papers of the Pfingsten and Downs accounts with unqestionably known measurements.

To eliminate inconsistent usage I recommend that in salamanders body length is tip of snout to posterior end of the vent, inasmuch as the cloaca, for which the vent is the outlet, is a derivative of the body, and tails rarely break off at the anterior end of the vent.

TERMINOLOGY

Gravid. Does this mean the same as pregnant? When a eutherian mammalian egg is fertilized and is *in utero* we say "pregnant." Eggs of amphibians and reptiles may become quite large and an animal carrying large, unfertilized ova is conspicuous externally or when opened; here "gravid" is a more appropriate term. If the ova are fertilized and are carried in the fashion termed "ovoviviparous," then pregnant seems the better term.

In the discussion of salamander S-V length I spoke of the cloacal opening or vent. In reptiles we normally identify the tail as beginning where the cloacal opening is situated, and here we have considerable awkward usage—the term "anus." Peters (1964) did not define anus, but in morphology the term means the terminal outlet of the alimentary tract, hence in mammals the end of the rectum. But in amphibians and reptiles the terminal part of the alimentary tract per se enters the cloacal chamber. Herpetologists refer to the outlet from the chamber as "vent" in salamanders, "anus" in frogs, toads, and reptiles. But the cloaca is a chamber into which digestive, reproductive, and urinary tracts may empty. Thus because the terminus of the digestive tract, the anus, is within the cloacal chamber we need a distinct term for the cloacal outlet.

Salamanders and crocodilians have longitudinal cloacal outlets, frogs, toads, caecilians, and turtles have circular openings, and snakes and lizards have transverse openings. The term "vent" certainly would be acceptable, with all references to body length therefore confined to snout to posterior end of vent. But because so many references to anus and vent are undefined I propose that we be definitive and say that body length is from tip of snout to posterior end of cloacal aperture in amphibians, turtles, and crocodilians, and in snakes and lizards we would say tip of snout to posterior end of scute covering the cloacal aperture.

We also have a peculiar adaptation of the adjectival term "anal." What is the name of the large scale that covers the cloacal aperture in a snake or most lizards? Virtually all herpetologists use the term "anal plate" or a comparable term such as "anal scute," "anal shield," or "anal scale," or just "anal." Peters (1964) gives the term "anal" (= anal plate) as the "terminal plate in the ventral series in snakes, usually larger than ventral scales..." and some varied synonyms. Peter (1972), at least, said cloacal or anal scale or shield. I object to the term "anal" for the same reason as I did in discussing S-V length. The term "anal" should be replaced by "cloacal" or "vent"; my preferred term would be "cloacal scute" or "cloacal scale."

But the term "cloacal" or "vent" alone does not solve the problem. Reptile bodies are covered by epidermal derivatives that we call scales, scutes, shields, etc., and dermal derivatives that are bone. Peters (1964) tells us that a plate is a large scale, but indicates that it has been used for bony elements of the turtle shell in contrast to the epidermal elements. Various herpetologists discussing turtles have used the term "epidermal laminae," "shield," "scute," and "horny laminae" for epidermal components, and the terms "plate" or "bony plate" for the bones of the shell.

Inasmuch as the dermal elements of the turtle carapace originate as flat, platelike elements separate from the chondral bones with which they may unite, I suggest that those dermal components be called bony plates to clearly distinguish them from the epidermal derivative. If we abandon the term "plate" in application to epidermal derivatives we need only to consolidate terminology of the epidermal elements.

The term "laminae" used by Carr (1952) was rejected by Zangerl (1969) because "lamina, e.g., Lamina cribosa" is a term used for bony sheets or plates in anatomy. Therefore I believe we should not apply "lamina" to epidermal elements. That leaves us free with shield, scale, and scute as possible synonyms for the epidermals.

The Squamata and the Testudines have large (an arbitrary value) epidermal elements that closely adhere to and cover bones, as, e.g., on top of the head. For these I have no objection to the term "shield," but a shield nevertheless is a scute or scale. Peters (1964) defined a scute as a large scale usually meaning much the same as plate, lamina, shield, and a scale is epidermal in his definition. Therefore I suggest that we restrict the term "shield" to large scales that are closely adherent to and cover bones. Large scales atop the head of snakes, lizards, and turtles can be called shields, much as the epidermal elements such as appear on turtle shells. For the scales of the soft snake or lizard body the term "scale" or "scute" suffices. In lizards, scales containing osteoderms probably should be said to be shields. Some scales, e.g., labial series, may pose a problem of usage. This would be negated if we get rid of the term "shield" and confine ourselves wholly to scute or scale for all epidermal derivatives.

The scutes of the belly of snakes and lizards have been referred to by several names: belly scales, gastrosteges, ventrals, but fortunately we seem to have stabilized at ventrals. But for the underside of the tail we have a problem. Conant (1975) used the term "subcaudal," sometimes shortened to "caudal." Stebbins (1985) used caudals. As I see it, any scale on the tail is a caudal, hence the appropriate term for those that we normally count on the underside of a squamate tail is "subcaudal." Some Australian herpetologists use an archaic term, urostege, which though understood to be the equivalent of subcaudal is really nonrestrictive because "uro" means "tail" and "stege" means "covering" (cf gastrostege, which is restrictive because the meaning "belly covering" is definitive). Thus I reject urostege as a synonym of subcaudal because the term could apply to any tail scale.

NOMENCLATURE OF TURTLE SHELL EPIDERMAL AND DERMAL COMPONENTS

Shell component nomenclature is badly confused and variable. Zangerl (1969) supposedly solved the dilemma, but subsequent usage has been diverse. Table 1, a compilation of terminology from various books and monographs, shows much of the variation in terms utilized. For example, the first median scute of the carapace has been called precentral, neural, cervical, and nuchal. For this and other scutes no clear consensus can be determined. Perhaps the most impressive

comments for a set of nomenclatural terms was given by Pritchard and Trebbau (1984). They stated that Zangerl's term "cervical" for a scute has little following. They did not like Zangerl's term "pleural" for a scute because that term is used more familiarly for underlying bones—the lungs are pleura, thus the bone closer to the lung should be a pleural. Scutes are closer to the more superficial ribs or costae, hence scutes should be costals. They also preferred to maintain Greek nomenclature for carapace bones and Latin names for scutes (but note that they are flawed in use of "nuchal," a Latin derivative, for both a bone and a scute). Whether we use Latin or Greek seems immaterial; latinization is the only necessity to conform to the language of biological nomenclature. I therefore propose the following set of names for carapacial elements (see Fig. 1):

BONE: proneural, neural, suprapygal (over the pelvic area), pygal, pleural, peripheral.

EPIDERMAL SCUTES: nuchal, vertebral, supracaudals for the last scutes on the margin and equivalent to what some might term "marginal 12," (11th in kinosternids, 13th in *Caretta*), costal, marginal. A few minor alterations will be needed to accommodate certain pleurodires.

NOTES ON THE NESTING ECOLOGY OF *Platemys macrocephala* IN THE BRAZILIAN PANTANAL

Platemys macrocephala occurs from the Pantanal and Rio Paraguai in southwest Mato Grosso, Brazil to northeast Paraguay and northeast Bolivia (Rhodin et al. 1984). The only information on reproduction of this species is based on Rhodin et al. (1984) who examined fifteen specimens and estimated the breeding season.

Here we present nesting data based on active nests which we found by walking on the banks of marshes, bays and burrow pits distributed along the Trans-Pantanal Highway at the Rio Alegre ranch (56° 59'W, 17° 16'S), in the Pantanal, municipality of Poconé, Mato Grosso, Brazil. The Pantanal is a large (100,000 km²) seasonal swampland. The climate and habitat characteristics have been described by Prance and Schaller (1982) and Cintra (1985 a, b; 1987).

We recorded the habitat, location and dimensions of nests (Table 1), eggs (Table 2), and the dimensions of adults and a hatchling that hatched in captivity (Table 3). Oélio Falcão found a nest under construction in April. We examined two nests found in clay soil on the margins of a marsh and one in sandy soil in an abandoned pasture. One individual was observed building a nest at 1800 h. The turtle urinated, softening the soil and dug a hole with its hind legs. Of the two nests found in clay soil, one was under construction and the other had been destroyed by a predator (Crested Caracara, *Polyborus plancus*) which had eaten 50% of the eggs. The eggs of this nest were in two layers. The four surviving eggs were in the deepest part of the egg chamber, and were collected and maintained in a small box with cottonwool. One young hatched after six months. The upper part of the carapace, plastron and sides of neck were covered in orange/red patches. The pupils were gray and the iris buff.

Clutch size ranged from four to eight eggs/nest. Eggs were completely white, rounded and about three cm in diameter. The egg mass varied between 11 and 20 g (Table 2). The eggs have a porous surface and the shell is about 0.4 mm thick.

Three adult females and one adult male were collected from the wild and placed in captivity. All females laid eggs in captivity but the eggs were eaten by lizards (*Tupinambis* sp.). The adult female of 29.5 cm carapace length (Table 3) is the largest size recorded so far for this species.

The data presented here suggest that *Platemys macrocephala* starts breeding in the Pantanal near the end of the wet season (April-May) when the flooding of the Pantanal starts to recede, confirming the prediction of Rhodin et al. (1984).

Because *P. macrocephala* starts nesting at the end of the wet season, the eggs are exposed to high temperatures (up to 50° C at the surface of the soil) and low soil moisture during the dry season (June to November). The hard, calcified and relatively impermeable shells may be important to protect the embryos from dessication. Heavy rains occur in the Pantanal between December and March (Schaller and Crawshaw 1980; Cintra 1987) and we believe that it is in this period, when the soil is soft, that most hatching occurs.

ACKNOWLEDGMENTS

Oélio Falcão, Estelito Carvalho and Tito Correia de Arruda (deceased) of IBDF helped us with field work. We thank Bill Magnusson and Mark Hero for reading the manuscript. The Instituto Brasileiro de Desenvolvimento Florestal (IBDF) gave financial and logistic support for this study.

TECHNIQUES

A SIMPLE CODE FOR TOE CLIPPING ANURANS

A limited number of unique toe clipping codes have been proposed (see Ferner 1979 for a review). The most widely cited code is that of Martof (1953). Martof's system is appropriate if the study involves thousands of individuals. However, it has the disadvantage of requiring the clipping of many digits for even numbers of two or three digits (e.g., #16 requires clipping three toes, #66 four toes and #199 six toes). Clarke (1972) has shown that toe clipping toads reduces the probability of recapture, suggesting that the procedure may be detrimental to them. Underhill (pers. comm. in Daugherty 1976) also reported weight loss in toe-clipped *Rana pipiens*. Toe clipping may also reduce the mobility of arboreal frogs.

A system that minimizes toe clips is preferred. I have used the system shown in Figure 1. This system allows the first 99 individuals to be marked with only one or two toes clipped (Table 1) and involves the clipping of no more than three digits for up to 736 individuals, a number large enough to be adequate for many studies. After 99, not all consecutive numbers are available. When two amputations occur on one side of the body (left or right), the lower digit takes the higher value. For example clipping the first and third digits on the right hand side would represent

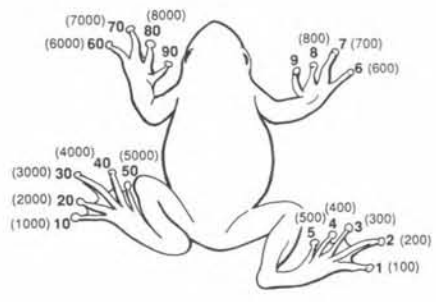

Figure 1. A simple code for toe clipping anurans. Note, when two clips are made on one side of the body, the number in brackets is adopted by the lowest digit (e.g. marking the first and third digits on the right foot would represent number 103 not 301).

the number 103, not 301. Hence it is then necessary to delete those numbers which become obsolete (e.g., number 301 cannot be used). Repeating marks can be avoided by using a table of clip codes (Table 1) and checking the codes as they are used. In addition to minimizing the number of clips, this simplified system is easily remembered, thus allowing more rapid marking and recognition of frogs in the field.

ACKNOWLEDGMENTS

I would like to thank Bill Magnusson and the Instituto Nacional de Pesquisas da Amazonia for their support and Lyn Cocceti from CALT at Griffith University for preparing the table and figure. This research was partially funded by grant no. 301299-86/ZO from the Brazilian Conselho Nacional de Desenvolvimento Cientifico e Tecnologico to W.E. Magnusson.

ARTIFICIAL HIBERNATION OF GARTER (*Thamnophis* sp.) AND CORN (*Elaphe guttata guttata*) SNAKES

Previous studies utilizing artificial hibernation for garter snakes report high rates of mortality (24% for adult females and 50% for adult males in Vagvolgyi and Halpern 1983; and 47.2% and 63%, resp., for adults in Joy and Crews 1987). During the course of our studies on chemosensory structures and functions in snakes, we have used artificial hibernation as a means of simulating natural conditions and lowering the cost of maintaining captive garter snakes (*Thamnophis* sp.) and corn snakes (*Elaphe guttata guttata*). The methods described below have provided a high survival rate for both adult and neonatal snakes. In addition, we observed robust courtship behavior and successful mating for both genera.

MATERIALS AND METHODS

All animals were contained in plastic sweater boxes (Hugh H. Wilson Co., Sunbury, PA), measuring either 40.6 x 27.3 x 16.5 cm (model 0957) or 40.6 x 27.3 x 9.5 cm (model 0956), with air holes in the cover. All snakes, except for *T. sirtalis parietalis*, were provided with pine shavings as a substrate. Three brown paper towels were used to line the bottom for *T. s. parietalis*. One bowl of tap water, cooled down to hibernating temperatures, was placed in each sweater box.

In September 1986, 50.50 adult *T. s. parietalis* were purchased commercially, group housed by sex, and maintained at ambient temperature (25° C ± 2°) for several days with water ad libitum. On 16 September, male snakes were separated into groups of 12 or 14/sweater box, and females were separated into groups of eight or 10/sweater box. All sweater boxes were then put into large cardboard boxes, which were closed and put into a refrigerated room (5° C ± 5°, but never below 0° C). A large piece of opaque plastic was placed over the cardboard boxes to prevent light from entering the boxes and to keep humidity high. No acclimation period was provided nor did we attempt to feed the snakes prior to hibernation. All snakes appeared healthy. Water and paper towels were changed every three weeks under red light illumination; otherwise the snakes were left undisturbed for 111 days (males) and 112-125 days (females).

On 16 October 1987, 12.15 adult *T. marcianus*, collected by the first author in LaSalle Co., TX and purchased commercially, were put into sweater boxes (four males/box and 3-4 females/box) and placed within an unlit low-temperature incubator (Queue Systems, Model 1210, Parkersburg, WV). On the same day, 7.7 adult corn snakes were put in sweater boxes individually and placed within the same incubator with the *T. marcianus*. All snakes were exposed to declining temperatures (16 to 10° C ± 2°) over 18 days. Water was changed every two weeks, and the pine shavings were not changed during the hibernation period. Prior to hibernation, these snakes had been maintained in the laboratory on a 12:12 h light:dark cycle at ambient temperatures. *T. marcianus* were fed as many goldfish as they would eat once/week, and the corn snakes were fed one adult mouse/week. Water was available ad libitum. Feeding was discontinued one week prior to hibernation. All snakes were brought out of hibernation after 73 days, directly into ambient room temperatures.

On 22 September 1988, 118 male and female *T. s. parietalis*, purchased commercially, were randomly distributed into sweater boxes (10 snakes/box) and put into hibernation as described previously for this species. Twenty-eight snakes were removed after 92 days in hibernation, 20 snakes after 99 days, nine after 119 days, 20 after 131 days, 10 after 153 days, and 30 after 180 days.

Table 1 shows the hibernation periods for corn snakes, *T. marcianus*, *T. radix*, and *T. proximus proximus* in 1988. All of these snakes were hibernated in the same manner as described for the snakes in 1987 except no acclimation period was given. These snakes were exposed to 10° C ± 2° from the onset. Juvenile corn snakes were not hibernated

during their first winter. Adult *T. radix* were purchased commercially in the summer of 1988. All neonate *Thamnophis* were born in captivity from pregnant females purchased commercially. Prior to hibernation, the adult and juvenile corn snakes were fed an adult or juvenile (5 g) mouse, respectively, once/week; adult *T. radix* and *T. marcianus* were fed as many goldfish as they would eat once/week; neonate *T. radix* were fed as much chopped earthworm as they would eat three times/week; and each *T. p. proximus* neonate was fed 2-3 guppies three times/week. *T. radix* neonates were also given vitamin supplements with each feeding (Reptical, Terrafauna Products, Mountain View, CA). Water was available ad libitum to all snakes, and all were maintained on a 12:12 h light:dark cycle at ambient room temperatures. Feeding was discontinued one week prior to hibernation.

RESULTS

Of the 100 snakes hibernated in September 1986, only one snake (a female found 50 days into hibernation) died (1% mortality). Although not quantified, males courted females with "chinning" and caudal undulations the day after removal from hibernation.

No deaths occurred among the snakes hibernated on 16 October 1987. Courtship was observed two weeks after removal from hibernation, lasting another two weeks. This reproductive activity resulted in three pregnant *T. marcianus* and six clutches of corn snake eggs.

Of the 118 snakes hibernated on 22 September 1988, only one male was found dead (0.8% mortality), at 37 days into hibernation. In every instance, courtship was observed from the day after removal from hibernation and up to two weeks afterward.

The results of all other snakes hibernated in 1988 are shown in Table 1.

DISCUSSION

The highest mortality (13.8%) occurred among the *T. p. proximus* neonates. This is still below the estimated mortality (45-85.5%) for natural populations of colubrid snakes surviving their first hibernation (reviewed in Parker and Plummer 1987; of course other factors, such as greater temperature and humidity fluctuation, availability of suitable hibernation sites, and predation upon emergence, may affect these results). Previous attempts to raise *T. radix* and *T. s. parietalis* neonates resulted in greater than 90% mortality when kept in constant laboratory conditions for over three months and fed only earthworms. These snakes would eat steadily for the first three months of their lives but would then refuse food. This refusal of food occurred in October. Under natural conditions, these species would have been in hibernation. Although artificial hibernation may help *Thamnophis* neonates survive by providing a necessary physiological shift, these previous mortalities may have been due to nutritional deficiencies (i.e. lack of vitamin supplements).

The most impressive results were found for adult *T. s. parietalis*, where less than 1% mortality occurred in snakes hibernated over six months. Prior to 1986, our artificial hibernation techniques produced up to 50% mortality in adult *T. s. parietalis*, probably due to dehydration. Previously, we hibernated our garter snakes as described in Vagvolgyi and Halpern (1983) and Joy and Crews (1987). In these studies, temperature and light regimes did not differ from this study, but snakes were placed in cotton bags with damp sponges and placed in light tight cardboard boxes. This method results in a quicker loss of moisture. Interestingly, Whittier et al. (1987) used clear plastic boxes for part of their study and report a mortality rate of 16.0 ± 1.5%. We believe that moisture availability is critical for long-term artificial hibernation as suggested by Constanzo (1985, 1988).

Vagvolgyi and Halpern (1983), Joy and Crews (1987), and Whittier et al. (1987) also used acclimation periods. Although we do not know how this interacted with the other hibernation procedures, we believe that temperature acclimation may not be necessary for successful overwintering, as suggested recently (Murphy and Campbell 1987). However, it should be noted that most of our data involves northern natricine snakes. Another study using southern species of *Lampropeltis* (Tryon and Murphy 1982) with acclimation procedures resulted in 0% mortality. It would be interesting to know if there are differences in survivorship during hibernation of northern versus southern snakes of the same species or between natricines and other colubrids.

Table 1: Results of artificial hibernation of adult and juvenile *Elaphe g. guttata* and adult and neonate *Thamnophis* in 1988 (except *T. sirtalis parietalis* - see text).

ACKNOWLEDGMENTS

We are very grateful to Dr. Neil Ford for generously providing us with *Elaphe* and *T. marcianus*, helpful advice and comments on an earlier version of this manuscript; to Dr. Ralph Gibson and Ray Pawley for advice on rearing neonate garter snakes; to Dr. T. Cox and E. Erichsen for helping with the dirty work; to Dr. Mimi Halpern for the support; and to Bern Tryon for helpful advice and comments. Adult *T. s. parietalis*, *T. radix*, and *T. p. proximus* were purchased from Wm. A. Lemberger Co., Inc. (Oshkosh, WI), and some adult *T. marcianus* were purchased from Snakes of Texas (Bruni, TX). This work was supported by NIH grant NS 11713 to Dr. Mimi Halpern.

ANURA

RANA SYLVATICA (Wood Frog). **ATTEMPTED PREDATION.** On 2 April 1988 at 2130 h (air temperature 11° C) an adult male *R. sylvatica* (58 mm SVL) was observed to bite and hold onto an adult *Notophthalmus viridescens* (SVL not recorded) at a breeding pond complex 0.75 km S of Jeffersonville, Sullivan Co., NY (390 m elevation). The frog appeared to maneuver the newt in its mouth as if to attempt swallowing, but after 2 min of struggling, the frog suddenly pushed the newt from its mouth into the pool. The frog wiped its mouth with its forelimbs, then swam to matted vegetation at the bottom of the pool. The newt floated still for several minutes before swimming to cover. Ten min later the frog began vocalizing. The "prey handling" activity exhibited by this frog suggests its behavior was not a territorial response, as reported for some ranids (Emlen S.T. 1968. Territoriality in the Bullfrog, *Rana catesbeiana.* Copeia (2), June 5. pp. 240-243), but was a predatory encounter. Apparently, the noxious character of the newt (Duellman and Trueb. 1986. Biology of Amphibians. McGraw-Hill Book Company, NY. pp. 250-251) thwarted ingestion by *R. sylvatica;* this is believed to be the first observation of attempted predation on *N. viridescens* by *R. sylvatica* reported. No specimens were collected.

CROCODILIA

ALLIGATOR MISSISSIPPIENSIS (American Alligator). **FORAGING BEHAVIOR.** Although the diet of juvenile alligators has been documented by Fogarty and Albury (1968. Proc. Ann. Conf. Southeast. Assoc. Game Fish Comm. 21:220-222) and Chabreck (1971. Proc. Ann. Conf. Southeast. Assoc. Game Fish Comm. 25:117-127), no published accounts of juvenile alligator feeding behavior in nature exist.

On 27 March 1988, I used binoculars to observe a juvenile alligator (TL ca. 1 m) from a distance of ca. 20 m in the Sabine National Wildlife Refuge, Cameron Parish, Louisiana. During five minutes of observation the alligator, which was floating at the surface in a long, narrow opening in emergent vegetation, performed a stereotypic feeding behavior ca. 10 times. The alligator first aligned itself parallel and adjacent to the vegetation, then rapidly pumped a forelimb up and down in the vegetation for one to two seconds, following which it opened and snapped its jaws shut in the direction of the limb. Upon completion of this behavior the alligator moved forward several cm to half a meter, then repeated the behavior. Foot-pumping was performed on either side of the body, but more often on the right. The behavior appeared to be an attempt to frighten or dislodge potential prey from the vegetation. Although I could not determine whether the alligator succeeded, it occasionally seized and promptly discarded bits of vegetation. The observed behavior is concordant with the prominence of aquatic invertebrates, small fishes, and aquatic vegetation found in the stomachs of juvenile alligators in southeast Louisiana (C. Brantley, pers. comm.).

I thank Dale R. Jackson of the Florida Natural Areas Inventory, and Richard A. Seigel of Southeastern Louisiana University for beneficial comments on an earlier version of this manuscript.

TESTUDINES

CHELYDRA SERPENTINA (Common Snapping Turtle). **FECUNDITY.** While collecting research materials on the Valentine National Wildlife Refuge, Cherry Co., Nebraska, in June 1988, we unearthed a nest of a common snapping turtle containing 104 eggs ($\bar{X}$ mass for 103 fertile eggs = 13.887 g, SD = 0.586 g). The nest was less than 24 h old when it was opened, because it was not present when we examined the site the preceding day. We judge that the nest held eggs laid by a single female, because the eggs were contained within a single chamber, they were fairly uniform in size, and no trace of damaged eggs was found nearby. Had the clutch actually been produced by two females ovipositing in the same cavity, a portion of the first set of eggs certainly would have been destroyed by the second female while re-opening the nest chamber.

Ernst and Barbour (1972. Turtles of the United States. The University Press of Kentucky, Lexington) reported that clutches of common snapping turtles range in size from 11-83 eggs. Our observation indicates that some individuals of this species actually produce in excess of 100 eggs.

CHRYSEMYS PICTA BELLI (Western Painted Turtle). **EGG RETENTION.** Aseasonal retention of eggs had been reported for a wild chelonian in *Lissemys punctata punctata* by Duda and Gupta (1978. Herp. Review 9:46.), who also reviewed reports of egg retention in other chelonian species, all of specimens in captivity. The authors felt that egg retention might be prompted by adverse seasonal weather conditions or lack of appropriate nesting grounds. Here I report a case of egg retention by a female *Chrysemys picta belli,* with notes on attempts made by the individual to nest.

On 9 June 1987 on the west shore of Middle Findley Lake on the Turnbull National Wildlife Refuge, Spokane Co., Washington, a female *C. p. belli* (plastron length 177 mm) was captured after partially constructing a nest cavity and then abandoning it without depositing any eggs. An X-ray the following day indicated the presence of 11 eggs. The female was observed attempting to nest in the same area on 11 June and 12 June, and made two attempts about 15 cm apart on the latter date. All four nest cavities were abandoned at a size that was probably inadequate for deposition of a clutch of 11 eggs, as judged from observations of nesting in this population and a nearby population in Latah Co., Idaho (Lindeman 1988. M.S. Thesis Univ. Idaho). All contacted immovable underlying basalt, and on one occasion the claws of the female's hind limbs made audible rasping sounds, scratching at the rock for several minutes before the cavity was abandoned.

The female was captured again on 24 June, and a second X-ray indicated that presumably the same clutch of 11 eggs (in the same relative positions) was still present. Palpation of oviducts indicated a continued presence of shelled eggs in the abdomen at the next three captures of the female on 25 June, 15 July, and 16 July, but not at the next capture on 12 August; thus eggs first detected somewhat early in the nesting season were retained by this female until at least 19 days after the last other record (27 June) of a gravid female in either population under study. The Turnbull Refuge is characterized by shallow soils covering basaltic formations, particularly around Middle Findley Lake. Prolonged retention of eggs by this female was very likely due to difficulty in finding suitable nesting ground with deep, rock-free soil.

CLEMMYS GUTTATA (Spotted Turtle). **REPRODUCTION.** There are apparently no published records of *Clemmys guttata* depositing more than one egg clutch in a single nesting season (Ernst. 1976. J. Herpetol. 10(1): 25-33; Ernst, pers. comm.). On 14 June 1988 a female *C. guttata* (CL=101 mm) kept in a semi-natural pond enclosure deposited a clutch of six eggs in a nest excavated in short grass about 4.8 m from the pond edge. Nineteen days later, on 3 July 1988, this same specimen deposited three eggs in a nest excavated about one m from the water's edge.

The female turtle was captive hatched and known to be in her ninth year. She was kept

under natural conditions after the first winter, and hibernated normally in the 0.24 ha enclosure. The diet was supplemented on an intermittent basis with Purina Trout Chow®, earthworms, and beefheart. It is significant that this specimen's total egg complement for 1988 exceeded the maximum published clutch size for the species (eight eggs, [Adler. 1961. Ohio J. Sci. 61:180-182]). The eggs were removed for artificial incubation; all eggs proved fertile. The first clutch produced five live hatchlings (the sixth died late in incubation); the second clutch produced three live hatchlings.

GRAPTEMYS CAGLEI (Cagle's Map Turtle). **SIZE MAXIMA.** Haynes and McKown (1974. Tulane Studies in Zoology and Botany 18:143-152) reported the maximum size of male (92.8 mm CL) and female (161.1 mm CL) *Graptemys caglei* from the Guadalupe River System of South Texas. A mark-recapture program was begun on the turtle populations of the Guadalupe River near Cuero, DeWitt Co., Texas, in May 1985. A total of 712 *Graptemys caglei* have been released, including 609 males and 103 females. Four hundred seventy-nine males and 57 females have been captured that exceed the previously reported size maximum. The largest male (CL=125.7 mm) exceeds the previous report by 32.9 mm, and the largest female (CL=202mm) exceeds the previous report by 40.9 mm. These specimens were 230 g and 920 g, respectively. Various of the largest specimens were photographed prior to release, and several specimens exceeding the previous size maxima are currently deposited in the West Texas State University Museum of Natural History, including both male (WTSU 11755, 11778-11781, 11785-11789, 11800-11802, 11804-11811, 11813-11815, 11818, 11820, 11894, 11898-11899, 11902-11905, 11908-11909, 11912-11923) and female specimens (WTSU 11790, 11816, 11819, 11900). Funding for the mark-recapture program was from the Texas Advanced Research Program (Grant No. 1157) and an Organized Research Grant.

PSEUDEMYS TEXANA (Texas River Cooter). **SIZE MAXIMUM.** McAllister and Lamar (1987. Life History Notes: *Pseudemys texana*. SSAR Herp. Rev. 18 (4): 73.) reported 30.5 cm as the maximum CL for *Pseudemys texana* in North-central Texas. This record represents an increase of 3.2 cm over the size maximum reported by Conant (1979. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 2nd Ed., Houghton-Mifflin Co., Boston. 429 pp). However, sexual dimorphism in size has not been reported.

A total of 561 *P. texana* (411 males; 150 females) have been caught and measured during a long term mark-release-recapture program, initiated on the Guadalupe River in 1985. *P. texana* larger than the previous size maximum have been deposited in the West Texas State University Museum of Natural History as voucher specimens.

We have noted a slight sexual dimorphism in size, with males being slightly smaller than females. Three females exceed 30.0 cm CL, but only one (WTSU 12009) (CL=31.9 cm/ 3080 g) exceeds the maximum size reported for the Northcentral Texas specimen by 1.4 cm. The largest female was caught in the Guadalupe River at US Alternate 90, 4 miles East of Belmont, Gonzales Co., Texas. The largest male (WTSU 11768) is distinctly smaller than the largest female (CL=253 mm/ 1792 g). This specimen was captured on the Guadalupe River at Cuero, DeWitt Co., Texas. Preliminary field observations indicate that clutch size varies in direct proportion to carapace length in this species. Thus, sexual dimorphism in carapace length in this species may have been selected for to provide maximum reproductive effort.

Funding for the mark recapture project was provided by the Texas Advanced Research Program (Grant No. 1157) and a WTSU Research Enhancement Grant.

SAURIA

ANOLIS SAGREI (Brown Anole). **BEHAVIOR.** The behaviors reported herein were displayed by brown anoles collected in a mobile home park in Melbourne Beach, Brevard County, Florida.

On 13 January 1988 a small newly captured juvenile anole (size not measured) was placed in a small cage containing two previously collected individuals. The larger of these two (SVL = 5 cm), a male, immediately attacked and began eating the juvenile. Apparently disturbed by observers, the large anole left the juvenile motionless on the floor of the cage, but a short while later it was gone and the large anole was noticeably plumper in appearance. Polis and Myers (1985. J. Herpetol. 19:99-107) included a report of cannibalism in *A. lineatopis* but not for *A. sagrei*. Fitch and Henderson (1987. Amphibia-Reptilia 8:69-80) reported several cases of intrageneric predation by *Anolis*.

Binder and Henderson (1982. Herp. Review 13:10) described tailwaving by *A. carolinensis* as a diversionary tactic used in the presence of saurophagous snakes. On several occasions, I observed individuals within a group of five captive *A. sagrei* waving their tails laterally in an erratic fashion similar to the motion of autotomized tails. Perhaps this behavior is also effective against conspecific predators.

I thank Joseph and Andrew Cochran for assistance in collecting anoles and Mary Lou and Nick DeNicolo for their hospitality.

CNEMIDOPHORUS LINEATISSIMUS DUODECEMLINEATUS (Whiptail Lizard). **NESTING BEHAVIOR.** The nesting behavior of several species of teids is well known (see Magnusson, W.E. 1987. J. Herpetol. 21 (4):307-316), but there is little information on the nesting habits of *C. lineatissimus* of the tropical dry forests of Western Mexico. On 6 October 1988, at the Estacion Biologia Chamela, Jalisco, Mexico, we observed two female whiptails excavating nesting holes. The holes were excavated in sandy soil in an open area devoid of vegetation about 1 m apart. Detailed descriptions of the climate and vegetation of this site are given in Bullock (1986. Arch. Met. Geoph. Biol. Ser. B36:297-316) and Lott et al. (1987. Biotropica 19(3): 228-235. The digging lasted ca. 10 min and the completed holes were 13 cm deep and 4 cm in diameter. After the excavation was completed the females deposited their eggs in the holes, taking ca. 20 min, and rapidly covered the nests. One female deposited five eggs and the other 5-7 eggs. We do not know how common it is for female whiptails to nest communally, and more data are required to assess the characteristics of nest sites chosen by *C. lineatissimus*. We wish to thank Carlos Martinez del Rio, Juan Pablo Gallo, and Edna Naranjos for their comments on this manuscript.

EUMECES OBSOLETUS (Great Plains Skink). **ESCAPE BEHAVIOR.** Some skinks (*Scincella laterale, Eumeces anthracinus, Eumeces septentrionalis*) are known to take refuge in water (Conant, R. 1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 2nd ed. Houghton Mifflin Co., Boston, 429 pp.; Collins, J. T. 1982. Amphibians and Reptiles in Kansas. 2nd ed. Univ. Kansas Publ., Mus. Nat. Hist., Public Ed. Ser. No. 8, 356 pp.; Taylor, E. H. 1936. Univ. Kansas Sci. Bull. 23(14):1-643). To my knowledge, this behavior has not been reported for *Eumeces obsoletus*.

On two occasions in Yuma County, Colorado, I have observed *Eumeces obsoletus* escape into water. In both cases, the skinks were active and in the open when I first saw them. The first occasion took place on 19 June 1983, along the South Fork of the Republican River a little upstream of Bonny Reservoir. At 0945 h, an adult skink wriggled down a grassy slope between me and another person as we tried to catch it. The skink quickly disappeared into the water. The second occasion took place on 29 May 1988, at a small pond near the North Fork of the Republican River, ca. 7 km E of Wray. At ca. 1700 h, I saw an adult skink beside a thick board near the edge of a shallow pond. As I approached, it wriggled over 30 cm of water and disappeared into a clump of emergent sedges. No conspicuous retreats appeared to be available for the first skink. The grassy area sloped steeply toward the water and contained no obvious rodent burrows or rocks that could have served as hiding places.

More potential refuges seemed to be available to the second skink. In addition to the large board near which I first saw it, yucca and other terrestrial vegetation was available a few meters up the gentle slope from the pond. In both cases, algae and other aquatic vegetation obscured my view into the water. Both times I felt around on the bottom of the water but was unable to locate either skink, and did not see either one return to land.

UTA PALMERI (San Pedro Side-blotched Lizard). **CANNIBALISM.** Cannibalism in iguanid lizards, which typically are insectivorous or herbivorous, is infrequently reported (Polis 1981. Ann. Rev. Ecol. Syst. 12:225-251; Polis & Myers 1985. J. Herpetol. 19:99-107), although in some populations it has been observed frequently (J. Stamps, pers. comm).

On 15 April 1987 we observed an incidence of cannibalism in the insular endemic iguanid *Uta palmeri* by an adult male (75 mm SVL) on a juvenile (ca. 40-50 mm SVL). We first observed the adult carrying the limp body of the juvenile, biting it at the middle of the trunk. The male then carried the body several m, disappearing under a rock for less than ten sec. He was next seen biting the body by its head and, after a few seconds, he began engulfment. His forelimbs were not used to assist in engulfing the body, but we observed small, side-to-side head movements during this period.

The frequency of cannibalism in *U. palmeri* is unknown. Wilcox (1980. PhD Dissertation. University of California, San Diego) observed an adult male carrying a dead juvenile, but was unsure if subsequent ingestion occurred. We and our coworkers have conducted over 3,000 man-hours of observation on *U. palmeri* during two-month field seasons in three different years (not always the same months each year), and have seen only this one case of cannibalism. However, only the 1987 field season coincided with a period when hatchlings and very small juveniles were abundant on the study grids.

U. palmeri is substantially larger in body size than other *Uta* (Ballinger and Tinkle 1972. Misc. Pub. Mus. Zool. Univ. Mich. 145:1-83) with adult male body size ranging from 70-80 mm SVL (Hews, unpublished data). Hatchling size ranges from 27-32 mm (N=7) (Hews, unpublished data) and thus a large disparity in size between adults and small juveniles might facilitate cannibalism in *U. palmeri.*

SERPENTES

COLUBER CONSTRICTOR PALUDICOLA (Everglades Racer). **FORAGING.** Two adult racers were observed employing widely searching foraging behavior. Although reports of diets and accounts of wild snakes swallowing food are fairly common, observations of prey capture are rare, and consequently foraging modes are poorly known (Siegal and Fitch 1984, Oecologia 61:293-301).

My observations were made on 3 January 1989 in Everglades National Park (Florida) at the boardwalk in Mahogany Hammock. Habitat was open mature subtropical hardwood hammock. Filtered sunlight reached the ground in several spots in the area snakes were observed. Shade temperature on the boardwalk at 1400 h was 27.4° C.

At 1346 h we heard a racer (ca. 100 cm SVL) emerge from a cabbage palm 6 m W of the elevated portion of the boardwalk. It foraged ca. 17 m in 13 min over a slightly circuitous path, passing under the boardwalk, and finally investigating and disappearing into an elevated cavity in a strangler fig at 1359.

At 1401 h a slightly larger racer (ca. 105-110 cm SVL) emerged from an upturned stump about 10 m S along the boardwalk from where the first snake disappeared. It basked briefly and then foraged 6 m S along the boardwalk. At 1412 the racer dashed forward after a treefrog. The frog jumped from the leaf litter to ca. 0.5 m up a treetrunk, and thence immediately to leaves of an adjacent shrub. The racer simultaneously turned from the treetrunk and cleanly picked the frog from leaves ca. 0.7 m off the ground. The snake moved immediately to a sunny patch and basked in a loose coil for 14 min (until 1429). It then foraged an additional 6 m S, climbing into a palmetto and onto the boardwalk. At 1439 it dashed down the palmetto and seized another fleeing treefrog. Foraging resumed immediately, and the snake vanished into a thicket at 1441.

Both treefrogs were brown and ca. 2.5-3 cm SVL, and thus were probably *Hyla squirella,* which I have seen in this hammock. In both cases the frog was swallowed less than 5 sec after capture. The second frog managed to emit a single squeak before being swallowed. I estimate that the foraging racers covered 31 linear meters in 25 minutes of movement (1.24 m/min). Both crawled steadily while darting the head side to side in arcs ca. 15 cm wide. They would occasionally stop to investigate an area more extensively, probing quickly into the leaf litter or investigating a log or stump. No rapid movements were seen except the two strikes at prey.

Over 40 people walked within 2-4 m of the two snakes from 1346-1441, and two walked past while the second snake was on the boardwalk. Neither species responded visibly to the other. The snakes seemed conditioned to ignore the steady human traffic, allowing us to make these observations.

CROTALUS SCUTULATUS SCUTULATUS. (Mojave Rattlesnake). **MATING BEHAVIOR.** We have seen references to the minimum length of the gravid rattlesnake (Klauber, L.M. 1972. Rattlesnakes. Univ. Calif. Press, pp. 175-176). However, we have no knowledge of reports that indicate the minimum age or length for copulation. This is a report of the copulation of two juveniles (both one year old) observed on 13 October 1988 in the Museo de Historia Natural, Facultad de Ciencias Biologicas, Universidad Autonoma de Nuevo León, San Nicolas de los Garza, Nuevo León, México. The snakes were siblings and were housed in a 5 gallon covered container laterally perforated. The male had an SVL of 523 mm; CL = 38 mm; mass = 111.2 g, and the female presented SVL = 435 mm; CL = 25 mm; mass = 101.3 g. The temperature in the container was 26° C. Copulation began at 0900 h and ended at 1726 h. The female shed before copulation; the male shed after copulation. We suggest that ecdysis of the female stimulated copulation in a manner similar to that reported for adult snakes. In reptiles, precocious sexual behavior has only been observed in turtles (Kramer 1987. Joint Ann. Meet. Veracruz, Mexico. Programs and Abstracts).

We thank David Lazcano for providing information, and Ivan Parra and Lea Andersen for criticism and suggestions.

Apolo. Hermosillo, Sonora, México ●

CROTALUS VIRIDIS VIRIDIS (Prairie Rattlesnake). **PREDATION.** Among viperids, mark-recapture studies have suggested that survivorship of young snakes is low, however, little information is available concerning causes of such mortality. The following observations concern prairie rattlesnakes that overwintered in a perennially occupied hibernaculum in Coal Creek Canyon, Carbon County, Wyoming in the spring of 1986. These animals were captured as they emerged, transported to camp for SVL and mass measurements as well as radio telemeter implants ($\bar{X}$ mass of telemeters = 3.4 g, range = 3.1 - 3.5 g), then returned to the den site for release.

On 27 May at 1130 h a 14.9 g, 28 cm snake which had a transmitter implanted surgically on 7 May was found dead and being eaten by many ants (*Formica* spp.). It had moved 57 m south between 2045 h on 25 May and 1620 h on 26 May. On 28 May at 2000 h a 14.0 g, 27 cm snake which had a transmitter implanted surgically on 3 May was found dead and being eaten by *Formica.* This snake had moved 35 m east between 1415 and 2000 h on 28 May. On 30 May at 1700 h an 18.2 g, 30 cm snake that had a transmitter implanted surgically on 28 May was found with its transmitter wedged between a rock and a sagebrush. Many *Formica* were on the snake and biting it, and there was a column of ants traveling between the snake and an ant mound. The snake was alive, although it responded very sluggishly to tactile stimuli. The snake had moved 36 m southeast between 1000 h on 30 May (when it was released) and the time of the above observation. Many ants clinging to it by their mandibles were removed manually and the snake was returned to camp where it died during the night. On 4 June at 1940 h a 9.0 g, 31 cm snake that had a transmitter forced into its stomach on 2 June was found dead and

being eaten by *Formica*. The snake was 30 cm from a large *Formica* colony. It had moved 48 m southeast between 1020 h (when it was released) and 1515 h on 4 June, and another 76 m south by the time of the above observation.

These four observations suggest that ant predation on small rattlesnakes may not be uncommon. Although in three of the four instances snakes were found dead (and thus could represent instances of scavenging rather than predation), the snake found on 30 May was alive, currently being attacked by ants, and died later presumably from toxins delivered via ant bites. Also, all of the snakes made lengthy movements (compared to mean daily movements for all neonates tracked in the spring of 1986 was 3.7 m; SE = 3.9; Graves, B. M. Unpubl. Ph.D. dissertation, University of Wyoming, Laramie) immediately prior to their deaths, suggesting that they were in relatively healthy states and that their movements may have brought them vicinal to foraging ant colonies.

ELAPHE BAIRDI (Baird's Rat Snake). **DRINKING BEHAVIOR.** On 13 February 1988, at 1600 h, a captive-bred (hatched July 1985) male *Elaphe bairdi* (TL = 136.9 cm, SVL = 89.54 cm), maintained in a 50.5 x 25 x 30 cm terrarium was accidently splashed with water. As beads of water on the snake's head rolled down to the upper labial scales, swallowing was observed. The water on the labial scales was drawn into the mouth while it was closed. This behavior lasted 42 sec.

This behavior was repeated 23 out of 24 trials conducted during the next 24 days. The duration of swallowing was 9-62 sec ($\bar{X}$ = 35.8, N = 25). Swallowing was observed when water touched the head, even though it did not always reach the mouth. During two of the trials the snake tilted its head and rubbed its labial scales along its dorsum, sucking water droplets off its body.

A bowl of clean water was always present and the snake has been observed drinking from it. Water falling on the head seems to stimulate swallowing regardless of the snake's hydration state. This may be a stimulus-response behavior that is an adaptation to living in an arid environment with limited standing water (e.g., west Texas). It would allow the snake to utilize water in the form of precipitation or condensation.

More complex variants of this behavior have been observed in the lizards *Moloch horridus* (Gans and Blumer 1982. Amphibia-Reptilia 3:57-64), *Phrynosoma cornutum* (Sherbrooke 1981. Horned Lizards. Southwest Parks and Monuments Assoc.) and *P. douglassii* (pers. obs.), and the snakes *Bitis peringueyi* (Louw 1972. Symp. Zool. Soc. Lond. 31:297-314; Robinson and Hughes 1978. Ann. Transvaal Mus. 31:189-193), *Bothrops asper* (Greene 1986. 99-108. *In:* Predator-Prey Relationships. Univ. Chicago Press), and *Nerodia fasciata compressicauda* (Miller 1985. Herp. Review 16:71). Unlike *E. bairdi*, these species have or appear to have scales modified to collect water.

I am indebted to John F. Lokke for providing me with the snake and its breeding history.

LOXOCEMUS BICOLOR (Burrowing Python). **SIZE.** Wilson and Meyer (1985. Snakes of Honduras. Milwaukee Public Museum, Milwaukee. 150 pp.) list *Loxocemus bicolor* as having a maximum recorded total length of 130.9 cm.

In the Dr. Rafael Lucas Rodriguez National Wildlife Refuge (Palo Verde), Costa Rica (10° 21'N; 85°21'E), eight live individuals of *L. bicolor* were measured during March and April, 1984. Their SVL measured to the nearest 0.5 cm in order of capture were: 1) 121, 2) 127.5 (UCR9376, female), 3) 129 (UCR8787, female), 4) 115, 5) 141.5 (UCR9375, female), 6) 75, 7) 79.5, and 8) 76.5. UCR initials indicate the catalog number of the specimen at the Museum of Zoology, University of Costa Rica. The fifth individual caught was the longest (SVL 141.5, TL 153 cm) specimen of *L. bicolor* that has been recorded anywhere.

The eight Palo Verde snakes were found at, or near, nests of *Ctenosaura similis* and *Iguana iguana*, whose eggs they are known to predate (Mora, J. M. 1987. J. Herpetol. 21:334-335). The nest sites lacked vegetation because of the lizards' burrowing activities. The nests were located in the interface between two types of habitat: fresh water swamps, where cattail (*Typha domingensis*) was the dominant vegetation, and the tropical dry forest.

We thank J. Monge and M.I. Di Mare for their help in the preparation of this manuscript. Financial and logistic support was provided by the Universidad Nacional, research project #780285 (Wildlife ecology and management in Costa Rica), and the Subdireccion de Vida Silvestre del Ministerio de Agricultura y Ganaderia de Costa Rica.

MASTICOPHIS FLAGELLUM (Coachwhip). **BEHAVIOR.** *Masticophis flagellum* is a large whipsnake that occurs in relatively warm, dry habitats across the southern half of the United States (Wilson 1973. Catalogue of American Amphibians and Reptiles. p 145.1). Behler and King (1979. The Audubon Society Field Guide to North American Reptiles and Amphibians, p 629) noted that *Masticophis*, when cornered, coils and vibrates its tail, and strikes repeatedly, often at the enemy's face.

Death feigning (letisimulation) has not been reported in this typically aggressive snake. On 16 April 1988, a large *M. flagellum* was collected by members of the Oklahoma State University herpetology class near Quartz Mountain in Kiowa County, Oklahoma. The snake was found in a mesquite grassland under a piece of corrugated aluminum siding. The weather was cloudy and rainy with the air temperature at 21° C. Upon capture, the snake was placed in a cloth sack and held for ca. one hour. Prior to release, the snake was handled extensively by the class; yet it made no attempt to bite and little effort to escape. While being handled the snake became limp. When released, it pushed its nose into the substrate, twisted its head and protruded its tongue in a manner similar to that of the hognose snake (*Heterodon* sp.) (Ditmars 1936. The Reptiles of North America, 291-292). When turned on its back it demonstrated fighting reflexes, but continued to tilt the head and leave the tongue out, rolling in the dirt. After ca. ten minutes of this behavior the snake was moved to tall grass and observed. Two minutes elapsed before the snake began to crawl away slowly.

This snake's actions may be due to its depressed body temperature, which would make any behavior requiring speed (e.g. biting, flailing, striking, etc.) extremely difficult. This observation suggests that alternate behavior strategies may be found in ectothermic organisms. The "typical" behavior observed during warm weather may be considered typical only because the animal is most commonly encountered in warm weather. During colder weather, when it is more difficult to move, perhaps alternate behavior such as letisimulation is the most adaptive behavior. Field and laboratory studies of known temperature specimens are needed to support this hypothesis.

MASTICOPHIS FLAGELLUM TESTACEUS (Western Coachwhip). **PREDATION.** On 18 June 1988, on the northeast bank of the Colorado River (35 km south, 24 km west of Coleman, Coleman County, Texas), we observed a male western coachwhip (SVL = 915 mm, TL = 1149 mm, mass = 190 g without prey items) preying upon a female western rough green snake (*Opheodrys aestivus majalis*; SVL = 396 mm, TL = 618 mm, mass = 21.2 g). The encounter lasted 3 h 49 min from when we first noticed the snakes at 0940 h.

We were drawn to the snakes by a rustle in the vegetation under a pecan tree (*Carya illinoinensis*) 7 m from the river. There we observed the coachwhip searching for the nearby, slowly-moving green snake. The coachwhip sighted the green snake as it was half-way up a 30 cm cedar elm (*Ulmus crassifolia*) sapling, and seized its dorsum just anterior to the cloaca. The green snake reacted by wrapping its tail around the coachwhip's neck and pulling the rest of its body into the branches of the cedar elm. After 28 min of occasional tugging by both snakes, the green snake was released. The green snake immediately crawled to the upper limbs of the cedar elm sapling. It was seized in the tail region after a short, seemingly-frantic search by the coachwhip.

After 2 h 7 min of repeated seizing of the green snake near the cloaca, the coachwhip finally grasped the green snake in the neck region. This was the coachwhip's first grip near the head in eight attempts. The green snake immediately bit the coachwhip on the

neck, but with no effect. The coachwhip then proceeded to swallow the green snake, but, the green snake's tail was completely entwined around a clump of nutgrass (*Cyperus* sp.), preventing the coachwhip from swallowing it completely.

The coachwhip spent the next 1 h 40 min attempting to free the half-swallowed green snake from the nutgrass. The coachwhip tried pulling from several different directions, and at one point even wrapped the green snake around a branch on the ground in attempting to dislodge it. The coachwhip also thrashed around and chewed on the tail near the knotted portion. Tail twitching by the green snake ceased about 25 min from being seized by the neck and partially swallowed. Finally, 3 h 49 min after first observing the encounter, the coachwhip pulled the green snake free. The coachwhip was immediately captured and the green snake and a sphinx moth caterpillar (Sphingidae: probably *Manduca* sp., but too mutilated for positive identification; TL = 57 mm, mass = 2.7 g) were palpated from it. After covering the caterpillar with dye (alizarin red) to enhance the teeth marks, it was examined under a microscope. Based on the size and spacing of the teeth marks it appeared that the caterpillar had been eaten by the green snake and then was regurgitated into the coachwhip's stomach.

The coachwhip was measured, marked, and released. The green snake and caterpillar were deposited in the Texas Cooperative Wildlife Collections, catalog number TCWC 66176. We thank J.R. Dixon for examining the caterpillar and determining which snake preyed upon it.

On 22 August 1988, one of us (JMM) witnessed the close proximity of a coachwhip and a green snake ca. 24 km upstream from the site previously described. This second site was 40 m above the FM 1929 crossing of the Concho River on the north bank. At 1200 h the coachwhip was seen foraging about 3 m above the water's edge in debris lodged in an American elm (*Ulmus americana*). The green snake lay on a live elm limb extruding from the debris ca. 2 m above the water and ca. 1.5 m from the coachwhip. To move from its limb, the green snake would have come in close proximity of the coachwhip. I (JMM) monitored the 2 snakes' activities for 3 h 30 min, during which the green snake remained motionless. The coachwhip failed to detect the green snake and moved away from it ca. 1 m. There it stopped foraging for the remainder of my observation. I believe it may have detected the green snake through chemoreception but could not determine the snake's exact location. The green snake may have survived this encounter due to its cryptic habits.

The abundance of both green snakes and coachwhips along rivers in this region coupled with the observances we have described above suggest that coachwhips may be keying in on green snakes as a prey species. As opposed to water snakes (*Nerodia* spp.) which usually drop into the river to escape danger, green snakes, once discovered, remain terrestrial or arboreal and try to survive through knotting their body around vegetation (see Hammerson 1988, Herp. Review 19(4):85). This leaves them vulnerable to predation by coachwhips.

We thank the Colorado River Municipal Water District for funding the project during which these observations were made. We also thank J.R. Dixon and B.D. Greene for their comments on this paper.

OXYBELIS FULGIDUS (Green Vine Snake). **REPRODUCTION.** A wild-born female was received at the Detroit Zoological Park on 28 April 1987 from an animal dealer. The animal was maintained in a stainless steel cage (L=56 cm, W=39 cm, H=32.5 cm) with branches and a water dish. On 5 May ecdysis occurred. Food (*Anolis carolinensis*) was accepted on 6 and 11 May. Ten adherent eggs were discovered in the cage on 19 May 1987. The eggs appeared desiccated, and were placed in a plastic container with a mixture of water and vermiculite in a 1:1 ratio (Tryon 1975. Bull. New York Herp. Soc. 11:33-37). After 24 h in this medium some of the eggs had rehydrated, and at this time the clutch mass was 53.2 g. Post-oviposition mass of the female was 148 g, SVL =115 cm, TL =167 cm. The eggs were incubated in the aforementioned medium at 27° C±2°. On 22 August, after 105 days incubation, two of the eggs hatched, and a third hatched the following day. Measurements of the hatchlings were as follows: A-SVL=23.1 cm, TL=36 cm, mass=3.3 g; B-SVL=21.7 cm, TL=33.5 cm, mass=3.7 g; C-SVL=25.6 cm, TL=35.7 cm, mass=4.3 g. A fourth egg slit, but the snake was found dead in the shell. The individual measured 22.8 cm SVL, TL=31.0 cm, mass=3.4 g. Mean values determined with the inclusion of the unhatched animal were: SVL=23.3 cm, TL=34.1 cm, mass=3.7 g. Fertility could not be determined in the remaining eggs. Fungal contamination of the entire clutch was noted after about 70 days incubation. *Aspergillus* and *Mucor* were cultured from the eggshells at this time.

The hatchlings were identical in coloration to their mother. They all exhibited the head-swaying behavior described by Henderson (1980. Milwaukee Pub. Mus. Contrib. in Bio. and Geo. 37:27-38). Subadult *Anolis carolinensis* were fed upon within 4 wks of hatching. One of the juvenile snakes died at the age of 5 months. Cause of death was undetermined. At 17 months the two surviving snakes were feeding on small mice, and had increased in size to: mass=85.2 g, SVL=81 cm, TL=111 cm, and mass 62.8 g, SVL=74 cm, TL=104 cm.

A computer search of the literature revealed little published information on reproduction in this species. Golder (1983.Salamandra 19:55-60) describes a captive breeding and the hatching of one egg. In that study the female suffered from dystocia, and oviposition was protracted over two weeks. Egg dimensions were L=5.1-49. cm, W=2.0-2.2 cm. In the present study eggs were not measured immediately after laying; however, the viable eggs were ca. L=3.0 cm, W=2.0 cm shortly before hatching.

I thank K. Koch for translation assistance, and M. Sulecki and L. Wachsberg for collecting data.

***PSEUSTES SULPHUREUS.* REPRODUCTION.** On 23 July 1987 the Columbus Zoo received eight *P. sulphureus,* exported from Surinam, and all in excess of 1.5 m SVL. On 1 August, a female of ca. 1.7 m SVL laid a clutch of 14 eggs. These ranged from 50-64 mm along the long axis and from 22-31 mm along the short axis ($\bar{X}$ = 55.9 x 27.1 mm). The clutch, which adhered into two masses upon laying, and seven single eggs, had a total mass of 395 g. Another female, ca. 1.5 m SVL, laid a clutch of seven eggs on 8 August 1987. These ranged from 52-72 mm x 20-22 mm ($\bar{X}$ = 60.0 x 20.6 mm) and from 36 to 44 g ($\bar{X}$ = 39.4 g). The second clutch failed to develop during incubation. Seven specimens hatched

from the first clutch on 24-26 October 1987 after 84-86 days incubation at a minimum of 28° C. Two additional specimens cut the eggshells and died within the eggs, although one of these was stunted and deformed. The seven hatchlings ranged from 350-418 mm SVL ($\bar{X}$ = 401 mm), and from 486-591 mm total length ($\bar{X}$ = 549.9 mm).

TYPHLOPS RICHARDI (Richard's Blind Snake). **ARBOREAL ACTIVITY.** Arboreal activity by leptotyphlopid blind snakes has been reported by Vanzolini (1970. Papeis Avulsos Zool 23:13-16) and later by Gehlbach and Baldridge (1987. Oecologica 71:560-563). Herein we report climbing behavior, presumably associated with foraging, in a typhlopid blind snake. On 21 February 1988 at 2030 h we observed a ca. 400 mm SVL *Typhlops richardi* climbing the trunk of a 30 cm DBH Papayo, *Metopium toxiferum*, in a subtropical xeric forest on Cayo Icacos, Reserva Natural La Cordillera, Puerto Rico. When discovered the snake was 1.5 m off the ground, only 33 cm below a large (0.75 m x 0.5 m) nest of the neotropical termite *Nasutitermes nigriceps*. The snake was clinging to irregularities on exfoliating bark of the tree and was slowly waving the head from side to side, constantly flicking the tongue as it climbed. On La Cordillera we have most commonly observed *T. richardi* beneath termite nest fragments partially imbedded in the soil (which are often associated with ant nests). We infer that the snake was climbing the tree to gain access to the nest in order to forage within it. After identification and measurement the snake was released at the point of capture. While we have never collected *T. richardi* from active termite nests, the senior author did collect a *Typhlops biminiensis* from an active termite nest in xeric forest on the U.S. Naval Base at Guantanamo Bay, Cuba.

NEW HERPETOLOGICAL RECORDS FROM ISLANDS OF THE GULF OF CALIFORNIA, MEXICO

In May 1985, as part of the project "Island's conservation from a sea in the desert," collections were made on Angel de la Guarda, San Lorenzo Sur, and Tiburón islands. New records were obtained which add to the distributions reported by Murphy and Ottley (1984. Annals of Carnegie Museum 53(8): 207-230).

Specimens are deposited in the Herpetological Collection of the Instituto de Biologia, UNAM (IBHUNAM), México, D. F. Identifications were verified by A. Ramirez-Bautista and E. Pérez-Ramos.

COLEONYX VARIEGATUS (Western Banded Gecko). BAJA CALIFORNIA NORTE: Isla Angel de la Guarda; southeast side of the island. 12 May 1985. A. Ramírez-Bautista and E. Pérez-Ramos. (IBHUNAM 5735-2). First voucher specimen from island.

TRIMORPHODON BISCUTATUS LAMBDA (Sonora Lyre Snake). SONORA: Isla Tiburón. 13 May 1985. A. Ramírez-Bautista and E. Pérez-Ramos. (IBHUNAM 5734). First record for island.

We would like to thank the University of California at Davis and The Nature Conservancy, International Program, for supporting the expedition through Dr. Enriqueta Velarde, and A. García for reading the manuscript.

BOOK REVIEWS

The Amphibians and Reptiles of Louisiana, by Harold A. Dundee and Douglas A. Rossman, Illustrated by Eugene C. Beckman. 1989. 24 color plates, 126 pages, 10 line drawings, XI-300 pp, 7½" x 10". Louisiana State University Press, Baton Rouge and London. Available from Louisiana State University Press, Baton Rouge, LA 70893. ISBN 0-807-1436-7, $29.95 + 1.50 h/p.

When I was a kid and saw a copy of Ditmars' *The Reptile Book,* I dreamed of writing up the herps of Louisiana. Years later, when Dundee and Rossman announced that they were going to do this publication, this dream came to an end. Instead, I gave them what support I could. Now, after years of waiting, the "herps of Louisiana" has become a reality, it is a very worthy testimonial to their efforts and I envy them their excellent product.

The book is divided into two parts. Part one consists of a short history of herpetology in Louisiana (2 pp), a summary of the distribution of amphibians and reptiles in Louisiana (6 pp), techniques for collecting and preservation (6 pp), the problem of snakebite (1 p), care of amphibians and reptiles in captivity (3 pp), conservation (1 p), species and subspecies (1 p) and common and scientific names (1 p). The remainder of the book consists of part two, the identification keys and species accounts (248 pp), followed by an excellent glossary (5 pp), literature cited (17 pp) and an index to the scientific and common names (4 pp).

Figures include a vegetational map of Louisiana, and drawings of salamander, anuran, turtle, lizard and snake structures used in keys. A map is included for each species, differentiating between those specimens examined (solid circles) or museum and literature records not examined (hollow circles). This can be somewhat misleading for some ranges, such as *Hemidactylus turcicus* (an

introduced species), p 213, where only six localities are listed with none for Terrebonne Parish (the reviewer's home parish) where it has been known for over 20 years.

The 24 color plates have from two (alligator) to 11 (salamander) items on each. The salamander, anuran and turtle plates depict the dorsolateral view of each species while some anuran groin areas are also shown. The lizards are shown whole for all except *Ophisaurus,* for which an adult and juvenile lateral view of the head end are shown. The snakes have a dorsolateral view of the head end with a patch of the venter of each given. In some cases a juvenile pattern is also included with an adult patterned form. The alligator plate consists of an adult and a juvenile. The color plates are excellent drawings of the various taxa and should be in themselves enough to identify most species without aberrant patterns or those that change significantly with age.

As stated in the preface, Dundee treated the amphibians and turtles while Rossman treated the alligator, lizards and snakes. This has produced some slight differences in the treatment of the accounts, but the uniformity is quite good for two such diverse people.

In the keys the salamander larvae and adults are treated in the same key while separate keys are used for larval and adult anurans. A novel key presents anuran sounds using phonetic characters instead of spectrograms. Anuran keys include graphs of seasonal reproductive features and calling temperatures; both are very good. Problem species in the state are lumped as one, e. g. the *Desmognathus fuscus-auriculatus* complex and the *Hyla chrysoscelis-versicolor* complex, and a lengthy review of the problem species in the state is presented.

A reviewer is expected to point out errors in a book of this sort. For the most part, the book is well edited. I was not able to find a single typographical error. The only other errors that I have been able to find are of a minor nature except one. A "key" map of the state should have been included. Louisiana has 64 parishes (counties of other states) and a map showing the location of these parishes would greatly aid someone using the distribution maps. While I have long been familiar with the various parishes, I still have to stop and think about the location of some of them.

On page 11 I question the statement specimens can be collected from a distance of 40 feet with a .22-caliber pistol with a smooth bore using dust shot. In my experience, 25 feet is the maximum accurate distance. On page 171, Grand Isle is stated to be in Terrebonne Parish but it is actually in Jefferson Parish. On page 212 a reference citation is given as P. K. Anderson et al. (1952) but in all other citations in the book, including this one used elsewhere, all authors are given. On page 228 the *Cemophora* distribution is stated to be flatwoods of St. Tammany Parish and the hill country of northern Louisiana; map 88 shows it also in Washington and Tangipahoa Parishes.

This is a book that I would recommend for every working herpetologist's library as well as for any bibliophile. It is filled with new information and it summarizes a large amount of previously published data. With the high cost usually associated with herpetological books today, the $29.95 price is surely a bargain.

Guide to Philippine Flora and Fauna. Vol. X. Amphibians and Reptiles, by Angel C. Alcala. 1986. Natural Resources Management Center, University of the Philippines xiv, 195 pp. ISBN 971-1026-28-7. Paperback.

This book is part of a 12 volume, detailed inventory of the Philippine flora and fauna. Special attention is paid to economically valuable and endangered species. The amphibians and reptiles of this archipelago are covered in the present volume. The author, a noted authority on vertebrates of the Philippines, presents information on 271 species (66 of amphibians and 205 of reptiles). Following the species accounts there are three pages of references, a glossary, and indices to common and scientific names.

This book is not a field guide. There are no identification keys, and not every species is illustrated. Therefore most species cannot be identified with high certainty. Many of the illustrations are taken from Taylor's monographs or other published sources, and are not always of the best quality. Others are of preserved specimens, some of which are poorly preserved and may not accurately represent the living animal (e.g. *Staurois natator,* p. 30). On the other hand, this book does assemble a comprehensive photographic collection (176 photographs and illustrations) of Philippine herps and for this reason alone fills a long-standing need.

The species accounts are not clearly organized. Most species are listed alphabetically within the genus, but there are numerous exceptions, making it difficult to find individual accounts. Although the date of publication is given as 1986, and despite the statement (p. iii) that the text has "been updated with the latest data added," it appears as though the text is current only to about 1979. Many recent taxonomic changes are not noted, e.g. *Draco evereti, D. quadrasi,* and *D. rizali* are now considered synonyms of *D. volans* (Inger 1983, Musters 1983). Important recent references, including some published in the Philippines, are not cited (Brown and Alcala 1980, Rabor 1981). Other critical references are not cited, for example Vol. 2 of De Rooij 1917 [the snake volume] is not cited, although Vol. 1 is cited. Surprisingly, the major recent monograph on Philippine amphibia (Inger 1954) is not mentioned in the Introduction, although a monograph on Bornean amphibians is cited (Inger 1966) (p. 1).

The author notes (p. 2) that 64% of the amphibians and 62% of the reptiles of the Philippines are endemic. This may be true but I hesitate to accept his figures. He incorrectly defines "endemic" in the glossary as including "indigenous" species, citing species as being "endemic" that are of limited occurrence in the Philippines but that do occur elsewhere (e.g. *Xenopeltis unicolor*). There are a few surprising omissions in the text. For example, the photograph and description of *Xenopeltis unicolor* are of a young specimen; adults lack the light collar. This is not mentioned in the text. Also, I would disagree with the author as to the function of the laterally expanded toes of *Hydrosaurus pustulosus.* Rather than being used for "swift swimming movements" (p. 88), I suspect instead that they function during bipedal running upon the water surface. This behavior has been recorded in the literature but is not mentioned by Alcala.

The book is adequately manufactured, although many of the photographs are poorly reproduced. The quality of the editing was reasonable, although a few typos remain (*Polypedates leucomystax* repeatedly spelled *"leucomystar"*; "vascular" defined in the glossary as "eardrum"). However, given the political and economic conditions in the Philippines we are fortunate to have the book at all. The author is to be commended for his efforts.

Despite the shortcomings, the book succeeds in presenting a needed summary of the current knowledge of the Philippine herpetofauna for the education of the public and for the guidance of future generations of students (hopefully many from the Philippines). It will be a useful reference for some time to come and should serve as a baseline for much-needed future studies.

Know Your Snakes, Vols. 1 and 2: Venomous Snakes of the Southeastern United States, produced and hosted by Okefenokee Joe. Anhinga Productions, Route 1, Box 660, Odum, Georgia 31555. 1988. $49.95 each or $99.95 for the set of two, including a teacher's manual. Approximate running time: 50 minutes total.

In the last ten years or so, there has been a true revolution in the entertainment/education industries, that revolution being "Video." In a remarkably short period of time, video has simultaneously become the number-one money maker for Hollywood, and a major tool for the education of millions of American students ranging from kindergarten to college and beyond. While the video revolution has produced a number of rather inane products, it has also enabled producers to put out some pretty interesting fare. One such program is Okefenokee Joe's series on the venomous snakes of the southeastern United States.

I was admittedly skeptical when I first heard about these tapes, but that initial skepticism quickly faded as I watched the programs. In short, both volumes of *Know Your Snakes* are very well thought out and produced. The series was produced with novice reptile hobbyists, nature centers, and school educational programs in mind. The experienced herpetologist will probably not find any new information here, but there are other reasons why such an individual would find these tapes to be a good investment, as detailed below.

The two-part series is attractively packaged with full-color covers. Tape 1 concerns the three rattlesnake species indigenous to the southeast. Tape 2 discusses the coral snake, the water moccasin, and the copperhead. The series was produced as a video field guide; each species discussion includes a range map, comparison with sympatric nonvenomous species, and discussions of preferred habitat, prey preferences, and behavior.

Tape 1 begins with a scene showing Joe poling his way through the swamp in a flat-bottomed boat, with the song "Swampwise" playing in the background. The narrator introduces Okefenokee Joe as a freelance naturalist and expert on herpetology. The scene then shifts to a red rat snake that Joe plucks from the trunk of a tree. He proceeds to explain why snakes are so misunderstood yet play such a valuable role in nature.

At this point, the program moves on to an in-depth discussion of the Eastern diamondback rattlesnake. The snake is shown in a variety of situations, including an interesting sequence in which one specimen comes across what appears to be a nest of young wild rabbits, which it quickly dispatches and eats. This section lasts about five minutes, as do the following sections on the timber rattlesnake and pigmy rattlesnake.

Tape 2 follows the same format as Tape 1, but covers the water moccasin, the coral snake, and the copperhead.

The information contained in the two-tape series is quite accurate, with one exception. In tape 2, Okefenokee Joe remarks that coral snake venom is neurotoxic and acts on the central nervous system. Technically this is not correct, as the symptoms of coral snake envenomation are produced by blocking at the neuromuscular junction, which is part of the *peripheral* nervous system.

From a technical standpoint, *Know Your Snakes* is well produced. The vivid colors and good definition of the picture could only come from a high quality broadcast-type video format. Each section moves along well, with good pace and little added fluff. The actual shots and scenes used are well chosen and look very natural. Unfortunately, at times Okefenokee Joe's own on-camera narration fades a little indicating a poorly-placed field microphone; the problem doesn't happen often, however. Another problem appeared during the cottonmouth-eating-fish sequence. There was a strange background noise during this section. I listened to the sequence several times but was unable to identify the source of the noise, which was quite distracting.

As a field guide, *Know Your Snakes* presents its subject matter in a way that can never be matched by any book. Simply put, still photographs can never portray a living animal as realistically as a motion picture can.

Know Your Snakes will make an interesting and valuable addition to any herpetological library. And as an educational tool for schools, Okefenokee Joe's programs are perfect.

Euthanasia of Amphibians and Reptiles. 1989. Published by Universities Federation for Animal Welfare and World Society for the Protection of Animals, 8 Hamilton Close, South Mimms, Potters Bar, Herts, EN6 3QD UK. ISBN 0 90067 46 4.

As stated in the Preface, *Euthanasia of Amphibians and Reptiles* "reviews some of the biological and practical considerations relevant to the killing of amphibians and reptiles and attempts to make clear recommendations for humane methods." The report points out that often it is the purpose for which an animal is killed that will dictate the technique utilized. Amphibians and reptiles are killed 1) in laboratories and schools for teaching purposes and research; 2) for commercial or industrial purposes; and 3) in emergency situations where veterinary surgeons and others are attempting to alleviate suffering. Methods of killing are divided into chemical and physical methods. In the report, barbiturates were considered the most suitable agents, but other chemicals also are mentioned including CO_2 (in certain situations). In response to this, the reviewer has used CO_2 in an attempt to euthanatize reptiles and anesthetize amphibians and has found it unsuitable.

With regard to inhalation agents, the report mentions that it may take hours for some ectothermic species to succumb to inhalation agents and may recover if removed from the system prematurely. Under physical methods of euthanasia the following are listed: 1) concussion, 2) shooting, 3) electrocution, 4) hypothermia, 5) hyperthermia, 6) decapitation and transection of the spinal cord, and 7) exsanguination of unconscious animals. The unsuitability of most of those methods is not stressed.

The major shortcomings of this report include: 1) lack of detailed listing of suitable chemical agents with recommendations on proper dosages; and 2) how to administer agents properly. The report should provide information on 1) sites for I.V. and I.P. injections in various groups of reptiles; 2) how to evaluate levels of consciousness; and 3) how one determines whether a reptile is dead or not. Auscultation of the reptile heart with a stethoscope is universally unrewarding in the live healthy amphibian and reptile. EKG machines and doppler flow detectors are useful. In any event, when an amphibian or reptile is unconscious, it should be decapitated. This will ensure it will not recover.

Two issues that were not discussed in this report concern the pithing of frogs and euthanasia of amphibians and reptiles collected in the field for museums. Pithing of frogs in the name of education can no longer be condoned. Likewise, killing of reptiles and amphibians in the field by lethal injections of/or submersion in formalin is unacceptable. Alternative methods, such as injection with a barbiturate or submersion in a solution of MS222 (for tadpoles), is easy and economically feasible.

Turtles and Tortoises of the World, by David Alderton. 1988. 191 pp., 98 plates (61 in color plus color frontispiece), 6 figures, 12 maps. Facts on File Publications, New York. $22.95

At first glance this is a beautiful book, reasonably priced, well bound, attractively printed on quality paper, and filled with excellent color plates and well-organized chapters. Unfortunately, the closer one looks at the book, the more disappointing it becomes.

In order, the book covers human-turtle relationships (a mere eight pages), anatomy and physiology (43 pp), reproduction (31 pp), and evolution and distribution (17 pp), as well as a family-by-family overview of all of those aspects (66 pp) and a taxonomic list to subspecies (with common names) of all the turtles of the world. Its coverage is thus much more even than previous general turtle books (especially in its laudable inclusion of many aspects of turtle physiology). I personally would have enjoyed more information on the population ecology of turtles, and some amateur readers will also lament the lack of a section devoted to husbandry.

Perhaps the single most significant omission is a literature cited section. A 28-item bibliography of secondary sources is included, but without reference in the text to primary sources it is difficult for the reader to check the "facts" presented. For example, we are informed: 1) that *Cuora* and *Terrapene* have more than one hinge (p. 20 and 21 and Plate 67; unquestionably only one) and *Kinosternon* only one (p. 21; generally two); 2) that turtles generally aren't aggressive toward each other (p. 59; see Lovich 1988, Herpetologica 44:197-222, or Berry and Shine 1980, Oecologia 44:185-191, among many others); 3) that green turtles breed when only four years old (p. 60; 20 to 30 years according to Frazer and Ehrhart 1985, Copeia 1985:73-79); 4) that the clasping organs of kinosternines are "on the inner surface of the hind feet" (p. 68; on the legs); 5) that "arid area" turtles ("temperate and seasonal tropical"; according to Ewert 1979, pp. 333-413 in Turtles: Research and Perspectives, Wiley) lay smaller eggs than those from tropical wet ones (p. 73); 6) that low fecundity in tortoises in explainable by group selection related to overgrazing (p. 75); 7) that the female marine turtle "invariably returns to the beach where she herself hatched (p. 75; an unproven hypothesis); 8) that the egg tooth "regresses" after hatching (p. 85; it is shed); 9) that hatchling marine turtles orient to the sea by the sound of the waves (p. 88; light is the cue most substantiated); 10) that the thecodont reptiles are direct descendents of the cotylosaurs, and thus the Archosauria and Lepidosauria are not sister groups (p. 93, Fig. 6; any modern text considers the latter sister groups); 11) that climate change was responsible for the Cretaceous-Tertiary boundary extinction event (p. 97; no mention is made of asteroids, vulcanism or fire storms); 12) that painted turtles only lay as many as 11 eggs (p. 125; to at least 23; MacCulloch and Secoy 1983, Can. J. Zool. 61:1499-1509); 13) that *Deirochelys* is "well able to prey on creatures bigger than itself, such as crayfish" (p. 128; unlikely even if the author means lobsters); 14) that "Box turtles are most commonly found close to wooded areas" (p. 133; not applicable to the Coahuilan and Ornate box turtles); 15) that musk turtles lay only up to 3 eggs at a time (p. 143; Tinkle 1960, Ecology 412:68-76, recorded at least 7); and 16) that *Pelomedusa* produces 40 eggs per clutch (p. 173; physically impossible based on Harding 1981, Bull. Chicago Herp. Soc. 16:86-94). Unfortunately, these are only a small fraction of the inaccuracies found in the text (see also Reimer 1989, Plastron Papers 18(6):11-13). I also found the combination of the King's English and a teleological writing style distracting.

However, the figures and photographs are generally of the highest quality, although fuzziness of Plates 26 and 46 should have precluded their inclusion and Figure 1 (a poor redrawing of Fig. 4 in Carr 1952) confusingly represents the ribs as being on top of the carapace. In keeping with the generally excellent job of editing, very few errors of orthography are perpetuated (but see *Kinosternon* on p. 142, *mawei* on p. 113, *yniphora* on p. 156, *sinensis* on p. 178, and *tristernalis* on p. 180). However, the legends are switched in Figs. 23 and 24 and a few additional typographical errors escaped editorial detection (e.g. pp. 61, 69, 114, and 166).

Having myself spent 15 years preparing a preliminary book on turtle distributions (1986, Checklist with distribution maps of the turtles of the world), I was at first pleased to see the family distribution maps, but then dismayed when several were transposed and incomplete (e.g. the lack of tortoises or emydids in Indonesia or *Clemmys* in California). Furthermore, in that same reference I attempted to be as objective as possible in recognizing controversial taxa (and then always with comment); however, the author seems usually to have followed my checklist, but in some cases to have obviously ignored it (as well as supporting published evidence) and used his own preferred names. This is even more problematical in several cases where the text and his taxon list disagree (e.g. the staurotypines are considered part of the Kinosternidae on pp. 24, 83, and 179, but as a separate family on pp. 142 and 145; *Pseudemys floridana hoyi* (no longer valid) is recognized on p. 128, but not on p. 176; and *Kinosternon abaxillare* has full species status on p. 144, but is a subspecies of *scorpioides* on p. 179). Data-based disagreement is fine, but inconsistency is inexcusable.

Last, but not least, I am not alone in finding serious fault in the author's repeated (pp. 7-8, 59, and 117) assertions that the solution to the problem of turtle conservation lies in farming them. This is a complete surprise to me given the record of the continued need of existing turtle "farms" to replenish their stock of adults or eggs from natural, often endangered, populations. The sound of Archie Carr's vigorous maligning of the turtle farm logic during my graduate student days still rings in my ears!!

In conclusion, this book is a pretty, but weak attempt to synthesize accurately our current knowledge of the turtles of the world. I can recommend it only for the basest amateur turtle enthusiasts, and definitely not for the professional or even for serious amateurs.

Reptile Egg-shells SEM Atlas, by H. Hermann Schleich and Werner Kaestle. 1988. Gustav Fischer Verlag, Stuttgart. 123 pp., $46.00 (hard cover).

The structure of reptilian eggshells has been neglected for a long time and only recently have more researchers become concerned with this topic. Thus, detailed studies of eggshells, especially those of squamates, are scarce. Schleich and Kaestle are to be commended for undertaking such a difficult task.

On the first eleven pages, the authors describe the characteristics of reptilian eggshells, shell morphology, functional morphology, and techniques for eggshell preparation. This introduction, followed by three pages of literature survey, is very helpful for a reader with limited knowledge of structural and functional aspects of eggshells.

In the main part of the book, the authors describe eggshells of four species of crocodiles, 17 species of turtles, and 51 species of squamates. Micrographs are presented on 38 plates opposed by pages with data of the specimens, the description of the shell structures, and schematic diagrams. The schematic diagrams are very helpful for the interpretation of the different shells and the features seen in the micrographs, especially for workers not familiar with eggshell structure. The authors put painstaking work into researching and compiling these specimens.

A section describing fossil reptilian eggshells from Germany concludes the book.

The SEM Atlas will undoubtedly become a major reference book for students, lay-people interested in eggshells, and even for specialists working in this field. It is a very good and welcome start with all its data, diagrams and illustrations, but it has its shortcomings.

In several cases the authors appear to have sacrificed diligent research in favor of presenting a large number of species. They do not refer to basic problems, or describe these too superficially. Several examples of this are given:

It is known to the specialist, but not to the uninformed reader, that some features of the eggshell structure may differ between eggs of feral animals and those raised in captivity. In rigid-shelled eggs the mammillary layer varies between freshly laid, incubated, and hatched eggs.

Fixation of eggs may induce structural artifacts. For these reasons, it is advisable to use material of consistently high quality in a work such as the SEM Atlas.

Abnormal shell material should be described in a separate section; otherwise it may confuse the unexperienced reader or even induce erroneous information.

Most of the pictured fossil gecko eggshells are multilayered, and therefore pathological. Ar et al. (1979) pointed out that the ability to hatch is based on the delicate equilibrium of all physiological features of egg and eggshell. The embryo will suffocate in multilayered shells with misalignment of the pores, or it will not be able to break through the double or multi-layered shell. The authors never mentioned this fact.

Important publications of reptilian eggshells are not cited in the literature review. These include extensive studies of crocodilian eggshell (Ferguson 1982); studies of turtle eggshells (Ewert 1979: Ewert et al. 1984; Packard

et al. 1982); studies of gas and water exchange, calcium mobilization, etc. (Packard 1982; Packard et al. 1984; Andrews and Sexton 1981; Sexton et al. 1979) It would have broadened the scope of the book if the authors had incorporated some of the results of the cited research.

It is a questionable praxis to identify fossil eggs only by macrofeatures such as size, shape, and possibly a shell-like layer. Nature produces so many egg-like phenomena (wasp burrows, worm holes, pellets, peloidal mudstones and so forth) that one can be mistaken. The specimens from Gaimersheim (Pl. 41, 42) and Offenbach (Pl. 43) fall into this category. The absence of any identifiable shell material or collapsed eggs, as is typical for soft-shelled eggs, makes the stated identification of these specimens very questionable. An egg-like look alone is just not enough evidence as Meyer (1867) and van Straelen (1928) have stated; some microstructural, elemental or mineralogical features of the shell layer should be identifiable.

Preparation techniques and research methods could have been further elaborated for persons who are unfamiliar with the SEM. As an example, mapping for calcite under the SEM will show more or less organized structural features of the calcite in soft eggshell. Although this is an SEM Atlas, other important procedures, such as light and polarizing microscopy, should be mentioned. It would have been very helpful if the authors had used arrows or letters in the illustrations to mark some of the features mentioned in the descriptions of the specimens.

Even with its shortcomings, the Atlas is a book worth having. It contains very useful data, and offers a good introduction to the topic of reptilian eggshells.

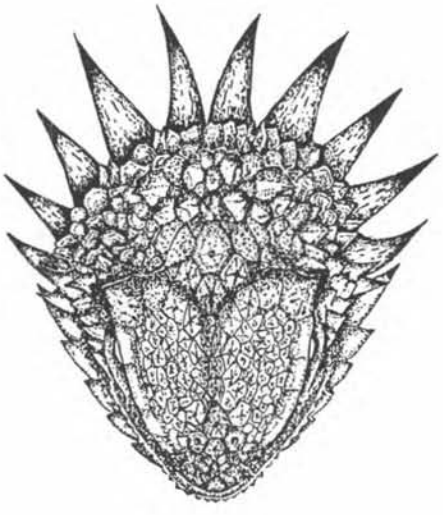
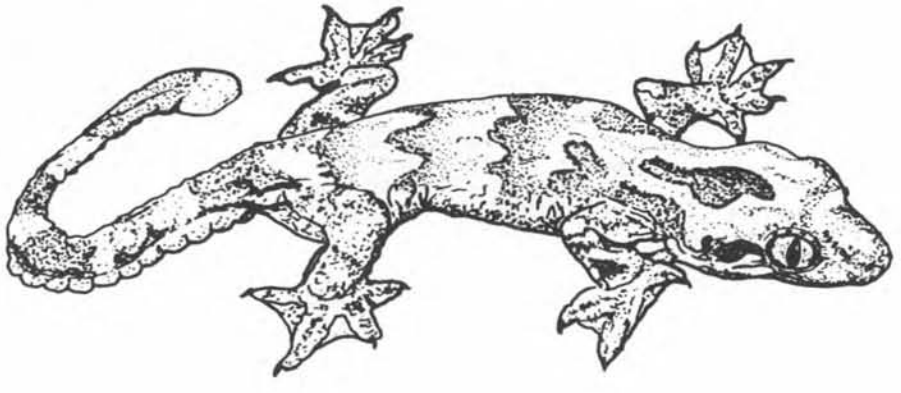
Frogs and Toads of the World, by Chris Mattison. 1988. Blandford Press, Poole, England. 191 pp. $22.95.

Amphibians in general, and frogs in particular, are becoming increasingly popular among herpetoculturists. This is good news, and long overdue. There will always be trends that come and go, but this change is broader than a trend. There has been a slow but steady drift towards increasing popularity of anurans in recent years. This is due, at least in part, to the breaking down of some of the myths concerning the "difficulty" of keeping these beautiful animals that naturally follows the publication of new books on the subject. Elke Zimmerman's *Breeding Terrarium Animals* immediately comes to mind. *Frogs and Toads of the World,* by Chris Mattison, will prove to be another force further pushing this drift forward.

In the introduction, Mr. Mattison lays out the aims of his work: He seeks to "provide insight into the varied lives of an interesting group of animals, produce answers to some of our questions and at the same time raise others." These aims are aptly met by this small but jam-packed book.



The herpetoculturist inherently knows of the intangible attraction that frogs and toads hold. With no slight to female herpetoculturists intended, the "boy-within-us" feels the mystique. Books deal in facts and figures, in words and illustrations—all tangible things, and with these the author must try to impart the intangible. He must engage the readers' imagination, tap into the mystique, as it were. Have you ever wondered why some people can regard, or rather disregard, anurans as "slimy—detestable" things while others are absolutely compelled to view them as infinitely beautiful and altogether fascinating? When a herpetoculturist reads this book there is a communion of kindred spirits between the author and the reader. What lies between the lines is what really makes this book a success! Chris Mattison loves frogs—he cannot help himself. I felt this as I read the book.



The title *Frogs and Toads of the World* sounds rather ambitious and all-encompassing. An exhaustive treatise on all the anurans of the world it certainly is not, but neither does it claim to be. What it is, is a good general introductory survey book. I use the word "introductory" without meaning to imply that the more advanced frog enthusiast would not find it valuable as well. The author makes no assumptions concerning the readers' knowledge of frogs, or lack thereof; this is good.

The chapters begin with the more general and progress towards the specific. There is an excellent balance of general anatomical/physiological information, natural history, and husbandry information. The text flows well, and is easily readable, as these various topics are discussed. Each chapter builds on the one before it. When you finish reading the book you will know more about anurans than you did before, and you will have a sense of the whole picture. The photos, both the color and the black & white, are excellent and plentiful.

In summary, I consider this book to be a valuable addition to my own library. My only regret is that I did not write it. What higher compliment can a reviewer pay an author?

Herpetofauna News

The Independent Voice of Reptile and Amphibian Conservation

Subscribe to *Herpetofauna News* and keep in touch. A subscription to *Herpetofauna News* brings you up to date news, views, features, announcements of meetings, book reviews and more. You are supporting the conservation of amphibians and reptiles worldwide.

When you subscribe to *Herpetofauna News* you are joining a body of people who actively support conservation of snakes, lizards, frogs, salamanders, crocodiles, sea-turtles, tortoises and other herpetofauna and the habitats in which they live.

Public Awareness	Your support helps publicise conservation problems and brings pressure for change where herpetofauna and their habitats are threatened.
Action	Your articles, reviews, and direct response to appeals creates action where it counts; both in the field and in Government.
News	Your information brings together up to date news on events and decision which will influence the survival of endangered species both in Europe and Worldwide.

Herpetofauna News is continuing as a result of the hundreds of requests to maintain production as an urgent priority. In 1988 we canvassed your views through a special questionnaire. Over 95% of responding readers want:

- Worldwide News Summary
- More Pages
- More on Practical Management of Reptile and Amphibian Habitats
- More UK Content
- Advertising and Sales Items

Sponsored by Herpetofauna Consultants International and ACO Polymer Products Ltd.

See over for subscription details.

Herpetofauna News will be produced twice in 1989 with more pages and improved format, and aims to expand to at least three issues in 1990. Subscribers will be supporting the long term future of the publication, and for those subscribing now, we guarantee to freeze the price of *Herpetofauna News* in 1990.

Subscribe Now and Receive Additional Benefits

- Free back issue of *Herpetofauna News*
- Free entry to a book raffle: *World Checklist of Threatened Amphibians and Reptiles* by Brian Groombridge (I.U.C.N.). Published by Nature Conservancy Council 1988.

The Amphibians and Reptiles of Louisiana

HAROLD A. DUNDEE and
DOUGLAS A. ROSSMAN

Illustrated by
EUGENE C. BECKHAM

In the only detailed and comprehensive study ever published on the state's widely varied herpetofauna, Harold A. Dundee and Douglas A. Rossman describe each of the state's 130 species, providing information on each animal's life history as well as feeding, behavioral, and reproductive habits. They also offer a valuable discussion on taxonomy and taxonomic problems of the various species and provide keys for the identification of the animals. Exquisitely rendered color paintings highlight each species' significant structural features and markings. The Amphibians and Reptiles of Louisiana will prove useful and informative for professional and amateur herpetologists and students. Illustrated with 24 color plates, 126 maps, and 10 line drawings.

Please send me _____ copy(ies) of The Amphibians and Reptiles of Louisiana at $29.95 per copy.

Please add $1.50 postage and handling for the first book ordered and .50 for each additional book.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** In 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to rtteview herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations and photographs. Manuscripts submitted must be typed, double spaced, on 8.5X11 inch paper, and should be sent in duplicate. We encouregе submissions on Macintosh disks, though we can also work with TEXT (ASCII) files submitted on IBM and compatible floppies. **Herpetological Review** is composed on a Macintosh SE using Microsoft Word, which accepts files from several other word processor applications. Format your documents full-page width; we will fit to **HR** format. Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8X10 inches black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. Herpetological Review will accept commercial advertising. Rates and copy information are available from the advertising manager. Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats. Contact the Managing Editors for details. All ads are accepted at the Editor's discretion.

Society For The Study Of Amphibians And Reptiles

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (4 issues annually), **Herpetological Review** (4 issues annually), and occasional issues of **Facsimile Reprints in Herpetology**. Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1989

Student member.....$25.00*	Sustaining member.....$50.00*
Regular member.....$35.00*	Contributing member.....$75.00*
Institutional subscription.$60.00*	Life member..(see below)...$600.00*

***Air delivery.** All memberships and subscriptions require a surcharge to defray air mail delivery costs if airmail is desired. Outside the US, $25.00; within the US, $12.00. Make checks payable to SSAR. A receipt will be sent only upon request. Payment in US funds only. Non-US members please remit in US dollars only by either international money order, draft on a US bank, or by Mastercard or Visa (include account number and expiration date of credit card). Life memberships may be paid in 3 consecutive payments

Subscriptions to Herpetological Review only are available for $12.00 annually. Subscriptions outside of the US require a surcharge of $8.00 for air delivery if airmail is desired. Subscribers to HR only are not members of the Society.

Catalogue of American Amphibians and Reptiles: subscription $15 annually ($3.00 air delivery surcharge if airmail is desired.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of SSAR. For membership information, contact the Treasurer (see address in left column).

Published quarterly by the Society for the Study of Amphibians and Reptiles at Meseraull Printing, Inc., RFD 6 Box 1, Lawrence, KS 66046. Steve Meseraull, Printer. POSTMASTER: Send form 3579 to the editor.

If you received such a copy, please return it to the Publications Secretary and a good copy will be mailed to you. Send to: Robert D. Aldridge, SSAR Publications Secretary, Department of Biology, Saint Louis University, St. Louis, MO 63103, USA. •

NEWSNOTES

LONGEVITY SURVEY

The Longevity Survey of Reptiles and Amphibians in North American Collections will be updated in 1989. Individuals and institutions that contributed data to the 1977 survey will be mailed forms in 1989. Those not included in the original survey may contribute data by contacting Kevin Bowler or Andy Snider at Audubon Zoo, 6500 Magazine Street, New Orleans, LA 70178, USA. (504) 861-2537. •

INFORMATION REQUEST

An annotated bibliography on amphibians and reptiles in the diets of North American raptors is being compiled. Raptor species to be included are: all falconiformes, owls, loggerhead shrike, and the common raven. Especially sought are papers that include frequency of occurrence and biomass data. Any information on poorly-known species is particularly desired. Contributors will be duly acknowledged. Please send all material to David A. Ross, Wisconsin River Power, Company, Box 8050, Wisconsin Rapids, WI 54495-8050. •

COLLECTIONS TRANSFERRED TO THE FLORIDA MUSEUM OF NATURAL HISTORY

The Herpetology Division of The Florida Museum of Natural History (formerly The Florida State Museum) has acquired the herpetology collections of Tall Timbers Research Station near Tallahassee, Florida, and The Florida State University (1800 and 4000 specimens, respectively). The majority of the two collections are from the Florida panhandle. The division now has over 44,000 specimens from Florida available for loan. For further information, or to arrange loans, contact David L. Auth, Collection Manager, Florida Museum of Natural History, University of Florida, Gainesville, FL 32611, USA. (904) 392-1721. •

GROUP PROTECTS COSTA RICAN RESOURCES

The Asociacion Preservationista de Flora y Fauna Silvestre was founded in 1985. It is a group of Costa Rican citizens concerned about poaching and illegal timber cutting activities within the country's forest reserve and National Park lands. It is also dedicated to the education of children in rural schools on wildlife issues. Members of the association are empowered by the government to arrest violators and confiscate illegal wildlife products.

This group is largely responsible for generating its own operating funds. Volunteers are in great need of funds for basics such as boots, flashlights and a tranquilizer gun for relocation of nuisance predatory animals. Contributions can be sent as bank drafts or personal checks to:

Asociacion Preservationista de Flora y Fauna Silvestre
Apdo. 8-4330-1000
San Jose, Moravia
Costa Rica, Central America

For more information please contact the group at the above address or: Kevin N. Brewster, Municipal Water Analysis Laboratory, Box 218, Eagle River, WI 54521, USA •

MEETINGS

DGHT ANNUAL MEETING

The Deutsche Gesellschaft fur Herpetologie und Terrarienkunde (DGHT) is holding its 25th Annual Meeting from 27 September through 1 October 1989, at the Senckenberg Museum in Frankfurt. Members of SSAR are invited to attend this meeting. For further information, contact Ingo Pauler, Im Sandgarten 4, D-6706 Wachenheim, West Germany. •

HERP COLLOQUIUM AT AAZPA MEETING

A special colloquium on the Conservation and Captive Propagation of Reptiles and Amphibians will be held in conjunction with the 1989 Annual Conference of the American Association of Zoological Parks and Aquariums in Pittsburgh, Pennsylvania 24 to 28 September. For details please contact Kevin Bowler at Audubon Zoo (504) 861-2537. •

ASZ CENTENNIAL MEETING IN BOSTON

The 1989 Centennial Meeting of the American Society of Zoologists with the American Microscopical Society, Animal Behavior Society, The Crustacean Society, International Association of Astacology, and Society of Systematic Zoology will be held 27 - 30 December at the Marriott Copley Place Hotel, Westin Copley Place Hotel, and the Copley Plaza Hotel in Boston, Massachusetts, during the traditional post-Christmas period.

Guest Editorial
HERP. REVIEW AT A CROSSROAD—AGAIN

I will preface these remarks by emphasizing that, as in any editorial, they represent my personal views rather than the official view of the Society. Therefore, send all hate mail to me at the address below!

Over the years, the folks who bring you this useful, nice publication have thrown themselves into its production in the tradition more typical of the regional society publications from which we developed. This is not said in derision, but in awe; what many publications (including some of SSAR's) pay printing firms ***large*** amounts of money to produce, HR and its regional society ancestors accomplish with ***large*** amounts of effort from the editors and managing editors. But, the last few years have plainly shown that SSAR is not attracting the number of new members, whose dues support our publications, as before. Income limitations, coupled with the amount of money spent to produce a first-rate *Journal of Herpetology*, have combined over time to limit what's available for those other SSAR activities that many of us feel makes SSAR special. No, I'm not leading up to suggesting a dues increase—I'm no longer on the Board, and never supported frequent increases anyway. My purpose here is to point out that HR's Editor elected to try something more innovative to give you—our core base of support—more for your money.

That something is a term we all hear tossed about, but may not know much of—Desk Top Publishing. Let me make crystal clear the fact that the term is a lie. It more accurately is Desk Top TYPESETTING/ COMPOSITION; publishing also involves volume printing and distribution, and unless *your* desktop is the size of the flight deck of an old Essex-class aircraft carrier you can't publish from it! But, it's a great technique. Going into this Volume, HR labored along under a *3-year* backlog of manuscripts incurred because there flatly wasn't money to publish them! The backlog now is close to **zero**. As a member of SSAR's committee to investigate Desktop technology (Harold Dundee, Chair), I last year thought HR would make a good model to test. An appeal last year for help brought three responses, but we had no real way to tell folks what to expect via time commitments and problems. So, new plan. My grand plan involved sharing the hat of Managing Editor, tapping people I knew who could type faster than in geologic time (my speed), and then doing the layout on my Macintosh SE. Marty agreed to try it. Thus, we composed 14 pages of HR 20(1) for the sum of $25, instead of the ca. $55 **per page** normal cost to take the publication to the printing threshold. In 20(2), we did 17 pages plus the Herp Values insert for about the same dollar cost.

But, dollars aren't the only cost; if they were, we'd mandate the method for all pubs and be able to return to the days when we could distribute Circulars free, set dues at $18, and do **all** the things SSAR has pioneered. Volunteer time and SSAR money are like matter and energy—they are interchangeable, but can neither be created nor destroyed! Well—not created, anyway. Part way through issue 1, my daughter opted to pursue more typical activities for a 14-year old than typing, though it was a "kick" for her to see her name on the cover. So, a friend and I did the rest of it, plus most key-stroking for issue 2. **NOT FUN.** Happily, Tom Johnson supplied Herp Values on IBM-type floppies, and I just transferred the file to HR in the Mac. But there, folks, is the biggest drawback to the technique—the tedious transfer of typed manuscript to the itty-bitty blips of electrical charge on a hard disk that are so easy (relatively) to format. No, I'm not whining for a pat on the head; I'm just typing out reality. And as I wear too many hats already (in and out of SSAR), I can take the effort no further. Also, having his own plethora of hats to wear, Marty would, as he expressed here last year, like to hand over HR to a new editor. Hopefully, that wish will be easier to realize now that a new recruit won't face the awful weight of that former backlog.

But, it sure would be nice if new souls would be willing to capitalize on what we've started here. It's not a job for anyone who lacks good support facilities like a laserwriter (in generic sense), a top-notch word processor (we use Microsoft Word© 3.02), folks to keystroke, etc. And, since the whole model involves graphics and is set up around Macintosh CPUs (yours truly has never successfully communed with MS-DOS machines), it would be nicest if brave new souls also liked and used Macs. But, the success of the technique depends ultimately less on hardware choices than on skill and determination. My recommendation would be for a new editor to recruit a Production Staff (some of the 3 early volunteers were agreeable to so working) to handle keying, and, ideally, a computer-fluent managing editor willing to help format (or do all of it), freeing the editor to deal with authors, reviewers, and budgets. We could probably come up with an additional managing editor here in Lawrence to interface with our printer, freeing the rest from worrying about the mechanics of getting the issues out.

That's our crossroad—all the above. SSAR was built on a tradition of volunteer effort, in a spirit that's hard to capture in a large society with members far and wide. But, volunteers have to pay bills, earn tenure and live their own lives, so the system only works if there are *lots* of people who understand and appreciate what others give, and in turn are willing to volunteer. The **only** alternative is the deadly spiral of paying escalating costs for services and financing those with higher tithes, which discourages new members (especially the younger ones whose involvement, or lack of it, determines the future viability of any group) and in turn pushes *up*, not *down*, the cost of belonging!

How about it gang—any takers??

George Pisani, Biological Sciences, University of Kansas, Lawrence, KS 66045

The Call for Contributed Papers has been issued by ASZ, and a 4 August deadline for receipt of abstracts of papers (oral or poster presentations) has been set.

Plenary lectures are scheduled the first three mornings of the meeting and include talks by Howard A. Bern, Joseph Bonaventura, Stephen J. Gould, Hugh Huxley, Masakasu Konishi, Gary W. Litman, George O. Mackie, Lynn Margulis, Keith Porter, Berta Scharrer, Marvalee H. Wake, and E. O. Wilson.

Symposia presently scheduled are: (1) Science As A Way of Knowing—Neurobiology and Behavior, (2) Animal Behavior—Past, Present and Future, (3) Frontiers in Hormone Research, (4) Application of Molecular Genetic Approaches in Understanding the Basis for Immune and Other Forms of Specific Recognition, (5) The Origins and Evolution of Metabolic Pathways in Animals, (6) Workshop on Invertebrate Habitats: The Ecological and Functional Biology of Endosymbiosis, (7) Workshop on the Teaching of Invertebrate Zoology, (8) Recent Advances in Phylogenetic Studies of DNA Sequences, (9) Experimental Approaches to the Analysis of Form and Function, and (10) Biology of the Thalassinoidea (Crustacea, Decapoda).

Meeting plans include art, book and instrument exhibits, programs on public affairs, ethics, and tools & technologies, several socials, commercial exhibits and a job placement service. The housing and registration deadline is 17 November; forms will be available mid-September.

This meeting is hosted by Harvard University and Northeastern University, with Karel F. Liem and Kenneth P. Sebens co-chairing the Local Arrangements Committee. Plan to join ASZ in the celebration of its 100th Anniversary.

For more information contact: Mary Adams-Wiley, Executive Officer, American Society of Zoologists, 104 Sirius Circle, Thousand Oaks, CA 91360, USA. (805) 492-3585. •

REGIONAL SOCIETIES

CHICAGO HERPETOLOGICAL SOCIETY
$2000 Prize Competition

The Chicago Herpetological Society is looking for high quality , original material not elsewhere published that deals with various aspects of herpetology. Towards this end the Society is offering cash prizes for the best articles and photograph to appear in Volume 24 (1989) of the CHS *Bulletin*, a monthly publication. The following four prizes will be awarded:

$1000 for the best article
$500 for the second place article
$250 for the third place article
$250 for the best photograph

Article topics could be, but are not limited to: captive breeding and husbandry; a faunistic survey or other field work; an historical account of herpetologists or the animals they studied; or an exciting personal adventure in herpetology; Articles must be typed double spaced, have adequate margins, and be submitted in duplicate. Articles submitted in the form of an ASCII file on a floppy disk would be greatly appreciated. Photographs submitted with or without articles must be 5 x 7 inches (or larger), glossy, black & white prints. Data on the subject must accompany the photograph in a typed caption of less than 100 words.

Submission of articles and photographs gives the CHS the right to publish the material. Awards will be announced in the February 1990 *Bulletin*. All material should be submitted to: Publications Secretary, Chicago Herpetological Society, 2001 N. Clark Street, Chicago, IL 60614, USA. •

ARIZONA HERPETOLOGICAL ASSOCIATION

The Arizona Herpetological Association is celebrating its 20th Anniversary in 1989. The organization was founded in 1969 by a handful of hobbyists interested in the conservation of reptiles and amphibians.

The Association publishes a bi-monthly newsletter, provides (among other things) educational talks and slide shows for the public and furnishes a free reptile removal service. Currently, the Association has nearly 300 active members.

Memberships are: $12.00 per individual and $17.50 per family. Benefits include six newsletters per year and free admission to all meetings and events. Events sponsored by the Association include field trips, mall shows and swap meets.

To become a member, send your check with name and address to:

Computerize Your
Field Notes and Collections

GECKO is a computer program for managing field notes and collections.

GECKO will allow you to:
Record genus, species, subspecies, number, locality, county, state, collector or observer, collection number and comments. Family, order and class are entered automatically.
Extract data for viewing, editing or printing by any combination of the above, e.g. iguanid lizard localities for Inyo Co, CA or all herps seen in Texas from June through August.
List data by order of entry, by date or phylogenetically.
Copy selected records to files for use with spreadsheets, word processors or data base programs.
Count number of species for all or part of the data base, e.g. number of species for 1988 or number of species of *Hyla*.

GECKO is very powerful, yet uses simple screen menus. It incorporates a master species list and is sold with your choice of the U.S. and Canadian list of herps, birds or mammals. Other species lists can be purchased separately and merged into a comprehensive list of terrestrial vertebrates. Lists can be easily edited to accommodate taxonomic changes or new species.
GECKO runs on IBM PCs and compatibles with 320K RAM and DOS 2.0 or later. $75 + $3 shipping. California residents add 6% tax. Please specify species list to be included. Additional lists are $25 each. Similar programs which use common names are available for all terrestrial vertebrates.

FEATURES

NOTES ON LOUISIANA GOPHER TORTOISE *(Gopherus polyphemus)* REPRODUCTION

Several recent surveys of gopher tortoises *(Gopherus polyphemus)* in Louisiana (Auffenberg and Franz 1982; Lohoefener and Lohmeier 1984) concluded that the species is critically imperilled to functionally extinct in the state. In 1986, the Louisiana Natural Heritage Program initiated an active search for gopher tortoises in southeastern Louisiana. To date, we have located active burrows at 18 sites. Although most of our sites are relatively isolated and support only one to three individuals, we observed 16 active burrows at one site in a powerline right-of-way, and nine active burrows at a site on private farmland. Prior to 1988, we had observed no evidence of recent reproduction (e.g., hatchlings or small burrows); therefore, our concern about the ultimate fate of gopher tortoises in Louisiana mirrored those expressed by previous researchers.

In September 1988, I obtained the first documented evidence of recent reproduction by gopher tortoises in Louisiana. In north-central St. Tammany Parish, two recently-hatched tortoises were found by the owner of a site known to support two active, adult-sized tortoise burrows. The first hatchling emerged at approximately 1000 h, 5 September; the second emerged about 24 hours later.

The nest had been excavated in the soil mound at the entrance to the burrow that I assumed to be that of the female parent. Upon excavation of the soil mound, I determined that the eggs had been laid ca. 12 cm below the soil surface and ca. 25 cm from the entrance to the adult burrow. The dimensions of the adult female's burrow were 36 x 14 cm (base x height), measured at a distance of 5 cm within the entrance.

The clutch included four eggs, three of which had hatched; the fourth was in an advanced stage of decay (deposited at LSU Museum of Zoology, LSUMZ 47920). Measurements of the two available hatchlings, taken at ages of 3 and 2 days, were: 6.4 x 4.8 cm (maximum carapace length x maximum carapace width) and 5 x 4.8 cm,

respectively. The older hatchling appeared healthy, whereas the second hatchling had suffered damage to the right eye from bites inflicted by red imported fire ants *(Solenopsis invicta)*. Landers et al. (1980) also documented attacks by fire ants on hatchling gopher tortoises and theorized that they may be a significant mortality factor.

Because pet and free-ranging dogs were common in the vicinity of the nest, personnel of Audobon Zoological Garden in New Orleans agreed to head-start the hatchlings for 1.5 - 2 years. The young tortoises will be released into suitable habitat on a protected site in Louisiana.

In addition to the resident female, the owners of this site reported seeing another large tortoise in and near the burrow excavated by the female during late spring or early summer 1988. However, I thoroughly searched the area within 300 m of the female's burrow and was not able to locate any additional adult-sized burrows.

The second case of recent tortoise reproduction in Louisiana was documented from Bush, St. Tammany Parish. The owner of this site noted two young tortoises and three small burrows 23 September; two more small burrows were located the following day. On 14 October, I visited the site and confirmed her identifications. One active adult-sized burrow and several inactive burrows were located on the site. The dimensions of the active burrow, presumed to be that of the female parent, were 30 x 16 cm. During my visit, I observed five active hatchling burrows (mean entrance dimensions 6.3 x 2.5 cm. and one inactive start; young were present in at least four of the five active burrows. Three of the burrows had been excavated at the base of some large object, such as a wood pile; the other two burrows were in the open. Total burrow lengths were about 25 cm (two burrows), 30 cm, and 45 cm (two burrows). All burrows were excavated at a shallow angle (ca. 15 degrees); thus, the burrow terminus was generally only 2-4 cm below the soil surface. Distances from the adult burrow to the hatchling burrows were 5.0, 7.8, 17.5, 22.9, and 70.1 m. I was unable to locate egg shell fragments or any other sign of the nest site. The resident female was uniquely marked, and the owners of the site reported occasional observations of non-resident adult tortoises on their property. However, I was unable to locate any active adult-sized burrows within 300 m of the presumed female's burrow.

These observations indicate that the gopher tortoise is not functionally extinct in Louisiana. Discovery of reproduction by apparently isolated female tortoises raises questions about gopher tortoise biology in need of investigation. Studies are needed to determine home range sizes of male tortoises under low-density conditions, and whether gopher tortoise populations can persist in non-"colonial" situations.

I would like to acknowledge Gary Lester, Louisiana Natural Heritage Program, for initiating the recent gopher tortoise surveys in Louisiana.

THE SAVANNAH RIVER ECOLOGY LABORATORY HERPETOLOGICAL MUSEUM

Herpetological research is a major emphasis at the University of Georgia's Savannah River Ecology Laboratory (SREL) in South Carolina (Gibbons 1977; Gibbons and Caldwell 1980; Gibbons and Patterson 1978). In recognition of the useful information that preserved reptiles and amphibians can provide for systematic, ecological and evolutionary studies, SREL maintains a representative museum collection of these animals. The scope of the collection is largely regional, but a variety of specimens from other states and countries are available. The purpose of the collection is three-fold. First, maintenance of a synoptic collection of reptiles and amphibians found on the Savannah River Plant (SRP). Second, to provide verification of important locality records with voucher specimens, and third, to provide interested researchers with a comprehensive regional collection for systematic, ecological and evolutionary study. The objective of this note is to familiarize the herpetological community with the amphibian and reptile collection at SREL.

Specimens entered into the collection date from 1950. However, specimens were not collected on the SRP and catalogued until 1968. Collection and preservation of specimens was in accordance with guidelines given in ASIH et al. (1987). Presently, the collection holds over 3000 catalogued alcoholic specimens representing 30 families, 80 genera, and 165 species. Of these, approximately 2000 are amphibians. The representation of major orders is shown in Figure 1. Major strengths of the collection include large series of local amphibians and small colubrid snakes, and an extensive collection of larval amphibians. Traffic volume on the 200 km of paved roads on the SRP is light, and road-killed specimens are rarely hit more than once. As a result, large numbers of freshly killed snakes have been collected and incorporated into the museum (Kaufman and Gibbons 1975). Regionally notable specimens include a significant range extension for *Rhadinaea flavilata* (Young 1988), and a collection of *Kinosternon baurii* from the western limit of their distribution in South Carolina (Lamb 1983a, b). Catalogued entries encompass 17 states with over 2600 records for South Carolina.

The entire collection was inventoried in 1988 and a computer file was created. Researchers interested in lists

of our holdings for various taxonomic groups or geographic regions can obtain them by writing to the Acting Curator of Herpetology. Loan policies are liberal, but visits are encouraged.

In short, we hope that research-oriented herpetologists will take advantage of the excellent regional collection maintained at SREL.

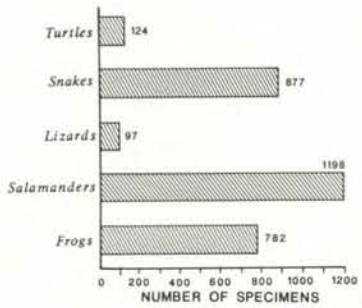

Figure 1. Number of catalogued entries for major orders of amphibians and reptiles in the Savannah River Ecology Laboratory Museum. Totals do not include lot catalogued entries.

FLORIDA STATE MUSEUM CHANGES ITS NAME BUT KEEPS ITS ACRONYM

The Florida State Museum was founded in 1917 by an act of the state legislature as a department of the University of Florida. FSM became the official acronym for citing specimens in print and remained in effect until 1946, when the museum temporarily closed its doors upon the retirement of its long time director, Dr. T.H. van Hyning. In 1951 the museum reopened and almost immediately, several collections maintained by the Department of Biology were transferred to its care, greatly increasing the museum's holdings. As a result of these transfers, the acronym was changed to UF, which remains in effect to this day.

A sign outside the museum reads "J.C. Dickinson, Jr. Hall, Florida State Museum" (Dr. Dickinson was the third director). However, another sign on the building declares "State Museum of Florida." Dr. Peter Bennett, fifth and present director, noted this discrepancy and also began meeting people in his travels who thought the Florida State Museum was located in Tallahassee and was part of Florida State University. He resolved to stop this confusion and, in June, 1988, the governor signed a name change into law. The Florida State Museum will now be called the Florida Museum of Natural History.

The logical new replacement acronym for UF would be FMNH, but it is already in use by the Field Museum of Natural History. In any event, abandoning UF would only add to the diversity of incorrect acronyms already present in the literature. For example, authors still commonly use FSM. UF/FSM and, less frequently, UF-FSU are also seen. Leviton et al. (1985) list both UF and UF-FSU as official acronyms for the Florida State Museum. Unfortunately, they don't mention in either their Parts 1 or 2 that UF-FSU refers only to a part of the Ichthyology Division collection, which was received from Florida State University (the Ichthyology Division is presently computerizing its collection and has dropped the UF-FSU acronym).

The Florida Museum of Natural History is one of the few institutions for which its acronym does not match its name. Although the present acronym has been in effect for 38 years, the new museum name will undoubtedly result in new incorrect acronyms in the literature. Authors should read the institutional loan form, on which the correct acronym is written (until recently, UF/FSM was on the Herpetology Division form!) or, in general, consult the appropriate person at the institution before submitting a manuscript.

UNUSUAL NEST SITE OF A SCINCID LIZARD *Sphenomorphus kinabalensis* FROM SABAH, MALAYSIA

Sphenomorphus kinabalensis is an endemic Bornean skink, known only from high altitude areas around Mt. Kinabalu, Sabah. Since Bartlett (1895) described this species, no information concerning its natural history has been published. In the present paper, we report an egg deposition site observed during a zoological survey in Sabah. Voucher specimens were deposited in the herpetological collection of the Department of Zoology, Kyoto University.

Sixteen eggs, covered by white parchment-like shells, were found in a nest of a ponerine ant, *Anochetus princeps*. The ant nest was made in tunnels (probably made by passalid beetles) in a fallen tree on the floor of the moss-forest at Ranau (near Mt. Kinabalu, alt. ca. 1300 m), Sabah, on 13 August 1987. All eggs were half-buried in the wet substrate of a brood chamber, where numerous larvae and pupae of the ant also were observed. We collected 14 eggs (elliptical, 9.8 X 7.9 - 13.8 X 9.4 mm), and kept them on wet paper in a plastic cup at an air temperature of 22° -32° C. Six of the eggs produced hatchlings, 20.1+ 27.5 - 21.5+28.3 mm snout to vent (SVL)+tail lengths, wheras the remainder molded. Exact dates of hatching were: 18 (N=1), 19(1), 24(1), 29(1), and 30(2) August 1987. We also examined five other fallen trees with similar tunnels in the same forest. However, neither lizard eggs nor ant nests were found.

We dissected seven adult female *S. kinabalensis* (SVL: 45.0-57.4 mm) collected near Mt. Kinabalu in August 1979, and examined their gonads. Of the seven animals, six possessed two oviducal eggs or yolked follicles, and the other a single oviducal egg.

The number of eggs found in the ant nest were probably the contribution of eight or more clutches, and thus, it is likely that the skinks specifically selected the ant nest as a communal oviposition site. The lack of eggs in other trees with similar tunnels but without ant nests support this assumption.

Among live lacertilian species, one teiid (*Teius teyou*) and one gekkonid (*Gonatodes humeralis*) are known to utilize ant nests as oviposition sites (Vaz-Ferreira et al. 1970, 1973; Gotwald 1984). However, no scincid species have ever been reported to lay eggs in any nests. Soldiers of *Anochetus princeps* are armed with stingers and large mandibles (Brown 1978), and therefore, it is likely that eggs of *S. kinabalensis* in their nests receive protection against small predators.

ACKNOWLEDGMENTS

We thank H. Heatwole for critically reading an early version of the manuscript, A. Taki and M. Kubota for identification of the ant, and S. Sengoku for literature. M. Ishii, K. Otsuka, S. Furukawa, and M. Matsui provided valuable company. Collection of the sample within Kinabalu Park was made under the permission of National Park Warden through the courtesy of F. Liu. Field trips to Sabah were financed by Grant-in-Aid for Overseas Researches from Japan Ministry of Education, Science and Culture (No. 62041049).

PREY ITEMS OF 20 SPECIES OF THE NEOTROPICAL COLUBRID SNAKE GENUS *LIOPHIS*

Liophis occurs in southern Central America, several islands of the Lesser Antilles, and throughout most of South America (Dixon 1980). At present, there are 36 species recognized in this genus.

While the taxonomic status and systematic relationships of many of the species of *Liophis* have been elucidated (Dixon and Markezich 1979; Dixon 1980, 1981, 1983a,b,c,d, 1985a,b, 1987; Dixon and Thomas 1982, 1985; Cunha et al. 1985; Myers 1986; Michaud and Dixon 1987), there still exists a paucity of natural history information for the majority of these snakes. The purpose of this paper is to present an overview of the diet of *Liophis*.

All *Liophis* have opisthodont dentition with simple teeth. There are 10 to 30 teeth on the maxillary bone; the last two are usually enlarged and offset, and separated from the others by a slight to moderate diastema (Dixon 1980). All teeth are ungrooved, including the two enlarged postdiastemal teeth. However, these postdiastemal teeth are proximate to one another with a large tube-like space between them that ostensibly might function like a venom delivery system, although we have no evidence that this is the case (for more information on dentition see Dixon 1980, pp. 22-24; and Edmund 1969, p. 177, fig. 41).

The majority of the species of *Liophis* are terrestrial, but some are semifossorial or semiaquatic. All species are usually found associated with moist environments. "*Liophis* are generally found around bogs, swamps, marshes, ponds, and streams that are associated with rain forests, montane forests, deciduous forests, thorn forests, grassland, and paramo." (Dixon 1980).

The occurrence of *Liophis* in these mesic habitats is reflected in its diet which consists largely of anurans and their larvae, and also includes insects, earthworms, fish, salamanders, amphisbaenids, lizards, birds, and mice (Table 1). Table 1 includes: a summary of the literature, the present contribution of a total of 11 new prey items for eight species of *Liophis*, the first report of any prey taken by *L. almadensis* and *L. paucidens*, and the addition of *Bolitoglossa altamazonica* and *Cnemidophorus ocellifer* to the list of species preyed upon by the genus *Liophis*.

While the present study adds to our knowledge of the diet of *Liophis*, it is apparent that there remains much to be learned. We can safely assume that the prey items listed for these 20 species are incomplete in most cases, and there are 16 other species for which the diets are unknown (*Liophis andinus, L. cursor, L. elegantissimus, L. festae, L. frenatus, L. guentheri, L. juliae, L. longiven-*

Table 1. Prey items of 20 species of *Liophis*. All present contributions are from dissected stomachs of snakes in museum collections, all presumed to have fed in the wild. All other prey items listed are assumed to have been taken by snakes in the wild unless otherwise noted. Prey items followed by (c) indicate that the snake ate the prey while in captivity, (ac) the snake attempted to eat the prey in captivity, and (w,c) denotes prey items that were consumed both in the wild and in captivity. Current taxonomic status (Frost 1985) of prey items are listed in parentheses when appropriate.

Snake Taxon	Prey Item	Reference
Liophis almadensis	frog eggs, probably *Pleurodema* or *Physalaemus*	This study
L. anomalus	frogs	Freiberg 1957
	frogs, toads, worms, insects, spiders	Freiberg 1982
	insects, *Bufo arenarum, Bufo granulosus dorbignyi (B. dorbignyi), Ceratophrys ornata, Leptodactylus ocellatus*	Gallardo 1977
L. atraventer	*Eleutherodactylus* eggs	Dixon and Thomas 1985 (W.R. Heyer, in litt.)
L. breviceps	earthworms, myriapods, *Synbranchus*	Beebe 1946
L. carajasensis	*Hyla, Leptodactylus*	Cunha et al. 1985
L. cobella	*Colostethus trinitatis, Thecadactylus rapicaudus*	Mole and Urich 1894
	fish, frogs, a gecko	Mole 1924; Wehekind 1955
	frogs, lizards	Beebe 1946
L. dilepis	*Hyla rubra (Ololygon rubra)*, unidentified hylid, *Leptodactylus ocellatus, Leptodactylus fuscus, Physalaemus cuvieri*, unidentified leptodactylid	Vitt 1983; see Michaud and Dixon 1987

tris, L. maryellenae, L. meridionalis, L. ornatus, L. problematicus, L. taeniurus, L. triscalis, L. vanzolinii, and *L. williamsi*).

Our knowledge of the feeding ecology of snakes, particularly that of tropical snake communities, will benefit from continued investigation of this widely distributed, speciose genus.

ACKNOWLEDGMENTS

The data on diets were collected over many years of taxonomic studies, and all the museums and individuals who kindly permitted us to borrow specimens of *Liophis* are acknowledged in those papers. We would again like to express our gratitude to the many people who extended us these courtesies.

TECHNIQUES

Hormonal Induction of Ovulation and Oviposition in the Salamander *Desmognathus ochrophaeus* (Plethodontidae)

There are two reasons for attempting to induce ovulation and oviposition in urodeles by endocrine manipulation. The first is to study these processes themselves; our understanding of the relevant endocrine events in urodeles is far from complete (for reviews, see Licht 1979; Licht and Porter 1987). The other reason is to obtain naturally fertilized eggs. Once eggs are available, it is possible to initiate studies of development and, if the eggs are the products of matings between different populations or species, of reproductive isolation and systematics.

In the Urodela, the endocrinology of ovulation and oviposition are best understood for the families Salamandridae and Ambystomatidae; plethodontid salamanders have received little attention (Licht and Porter 1987). However, a number of laboratories have induced ovulation in plethodontids, although not in any systematic manner. In this note, I describe an endocrine manipulation that safely and reliably induces ovulation and oviposition in the mountain dusky salamander *Desmognathus ochrophaeus*. Inseminated females of this species will lay eggs spontaneously in the laboratory, but only if they are left undisturbed for periods as long as six weeks (Houck, Tilley and Arnold 1985). Consequently, eggs may be at advanced developmental stages when removed from brooding females. The present protocol was devised so that eggs could be retrieved from females within hours of being laid.

Gravid female *D. ochrophaeus* (N=34) were collected from five localities in the southern Appalachian Mountains of North Carolina, Tennessee and Virginia during May and August 1987 and May 1988. In the laboratory, salamanders were kept at a temperature of 15±1° C on a natural (Chicago) photoperiod. They were housed individually in 9x17x31 cm plastic boxes, with a damp paper towel as a substrate and a crumpled damp towel for refuge. Each box contained two culture vials of *Drosphila*, replaced sufficiently often to ensure *ad libitum* access to food.

Female salamanders were paired with at least six conspecific males at irregular intervals from July 1987 until May 1988. They were used in a series of experiments conducted as part of an investigation of the evolution of sexual isolating mechanisms in the *D. ochrophaeus* complex (e.g., Verrell and Arnold, in press). The mating histories of all females were recorded, and each female had been inseminated by at least one male collected from her own population.

Attempts to induce oviposition were made in June and July of 1988. In the natural habitat, female *D. ochrophaeus* can be found brooding eggs from June to August, although some females may overwinter with their clutches (Tilley 1972, 1973). On the advice of several colleagues (Andrea Schmidt, Pere Alberch and Paul Licht, pers. comms.), an agonist of the hypothalamic releasing hormone LH-RH was obtained (Sigma Chemical Co., St. Louis, MO; des-Gly^{10}[im-Bzl-D-His^{6}]-LH-RH-ethylamide). This was dissolved in amphibian saline (of composition 102mM NaCl, 0.56 mM KCl, 0.23mM $CaCl_2$) to produce a hormone solution of concentration 50µg/ml. This solution was kept refrigerated.

Injections were given under ether anesthesia (1 part ether: 99 parts water). An intraperitoneal injection of 0.1 ml LH-RH agonist solution was administered through the ventral body wall, taking care not to puncture follicles. After injection, each female was placed individually in a clean plastic box as described above. Boxes were examined on subsequent days, and any eggs present were removed and placed in rearing containers (with careful husbandry, egg survival may approach 100%: Houck et al. 1985). Females that had not laid eggs after a first injection were given further injections of LH-RH agonist at various intervals (mean interval = 3 days, range 1-5 days).

Of the 34 females injected, all laid at least some eggs. Two females laid only partial clutches despite repeated injections; the other 32 (94%) laid complete clutches. In the former females, yolked eggs remained visible through the ventrolateral body wall after laying. The ovaries of spent females were visibly empty of yolked eggs. In the following analyses, only data collected from the 32 females that laid total clutches were considered (Table 1). No mortality was observed among these females.

The maximum number of injections of LH-RH agonist required to induce oviposition was six, although most females (91%) required no more than three injections. The maximum interval between the last injection given and the onset of egg laying was five days, although most females (94%) initiated laying after four days. The maximum time spent laying eggs (once laying had been initiated) was four days, although most females (97%) had laid a complete clutch after three days. Clutch size varied from 9-30 eggs (mean = 17.8, SD = 5.3, N = 32 clutches). The majority of females laid most of their eggs either between the leaves of the paper towel substrates, or between the towel and the box floor. Few eggs were recovered from the empty vials.

No formal controls (females injected only with amphibian saline) were used in this study. Over 100 uninjected females were present in the laboratory in June and July 1988, held for use in mating experiments in the fall. Most had mated with males from their own population at least once in May 1988. These females were examined ca. once every two weeks, and only one uninjected female was found to be brooding a clutch of eggs over the period during which injected females were laying.

Because of the considerable variability among females in their mating histories, no attempt can be made to correlate mating history with aspects of oviposition phenology or fertilization frequency. One hundred sixty eight eggs were subjected to the husbandry technique devised by Houck, et al. (1985). Of these eggs, 127 were from females that had not mated for at least two months before injection; 41 eggs were from females that had mated in early June 1988 (just weeks before injection). Respective percentages of eggs that developed to the prehatching stage in each of these two groups were 21.3% and 63.4%. Histological evidence indicates that female *D. ochrophaeus* may store sperm, in a viable state, for long periods (Houck and Schwenk 1984).

The LH-RH agonist used in the present study can safely and reliably induce ovulation and oviposition in *D. ochrophaeus* over relatively short periods of time. Assuming that this effect is mediated via the secretion of gonadotropin from the adenohypophysis, my results implicate a hypothalamic releasing-hormone as the fundamental regulator of gonadotropin release. In addition, an important role for this releasing-hormone in the control of egg laying is apparent. Eggs produced by this endocrine manipulation can be harvested from females shortly after they are laid, and thus are early in their development.

The data presented in Table 1 may be used to devise a standard protocol for the induction of ovulation and oviposition in *D. ochrophaeus*. These data indicate that a female should be

Monetary Values of U.S. Amphibians

Purpose

We herein provide a listing of monetary values of native amphibians that live or reproduce in aquatic habitats. These species are vulnerable to spills of oil and other hazardous materials. Until now there has been no scheme available to establish liability and economic compensation for the loss of this natural resource. Establishment of a system to quantify, in monetary terms, the loss of native amphibians from such an event may provide an incentive to industries and individuals to use greater caution when transporting, handling or using these materials. Financial penalties also may be useful in attempts to mitigate or repair some of the damage should such losses occur. It is, therefore, appropriate for the Society for the Study of Amphibians and Reptiles (SSAR), the world's largest organization of herpetologists, to publish and support these guidelines.

Background

Our society is finally realizing the fragile nature of wetlands and their value as a natural resource. Amphibians are a part of this complex habitat. It is hoped that from now on aquatic habitat quality and all wildlife associated with it—including native amphibians—will be taken into account when evaluating new projects or investigating chemical spills, unlawful sewage discharges or oil spills. The monetary value of the plants and animals that live in aquatic habitats must be considered as part of the cost of "doing business." Environmental law officers, lawyers and our courts need to recognize that the amphibians of the United States have a standing—a value in their own right and the right to exist.

Aquatic animals are especially susceptible to small quantities of hazardous materials that may be introduced into their habitat. Fish kills that result from such a circumstance can be very large and generate coverage by the news media at the state and or regional level. For a number of years, several state and federal fisheries agencies have investigated, evaluated and placed monetary values on the loss of fisheries resources following such fish kills. Although aquatic amphibians are often destroyed along with fish, little or nothing has been done to establish a dollar value for the lost resource. For example, a chemical spill in central Missouri during the fall of 1985 killed more than 17,000 fish in a two-mile section of stream. The chemical company that caused the spill and subsequent fish kill agreed to pay the state $47,792 for the accident. Of that, $3,131 was to cover the monetary value of the fish that were killed. A fisheries biologist investigating the damage also found 197 dead, adult green frogs *(Rana clamitans)*, but no attempt was made to add this loss to the final settlement because no monetary values were available for amphibians. The green frog is a game species in Missouri.

Since 1970, the American Fisheries Society (AFS) has published several lists, both on the regional and national levels, of fishes and their economic values. The organization's most recent publications, Monetary Values of Freshwater Fish and Fish-kill Counting Guidelines (1982, AFS Special Publication No. 13) and Fish Kill Investigation Procedures (1986), have served as the basis for establishing monetary values of lost fisheries resources resulting from non-natural fish kills nationwide. Resource biologists have expressed interest in a similar publication for native aquatic amphibians.

Data Collecting and Specimen Counting

Methods for collecting data and counting amphibians depend upon the type of habitat affected, the time of year, and the length of time that has passed since the chemical/oil spill. Investigation of a fish or amphibian kill must take place as soon as the accident or incident is reported. Larval or adult amphibians may sink to the bottom of a body of water and be lost if not collected or counted as soon as possible (especially during cold weather).

If the affected area is small and the quantity of animals is low, all dead specimens should be collected and preserved. If the size of the area and or the number of amphibians killed is large, an objective and defensible sampling technique should be used. This situation usually requires that sampling units be selected at random. The specimen-count area must be selected randomly to reduce the chance for biased results. It is recommended that the specimen-count guidelines specified in the American Fisheries Society publications cited above.

The final report of the resource damage caused by a chemical or oil spill should include a detailed account of the actual chemical or petroleum product(s) involved, size(s) of the total area(s) where counts were made, number of specimens estimated to have been killed in the entire area, the species involved, number of specimens counted or observed, and the total number of man-hours required to accomplish the investigation.

Specimen Identification

It is imperative that all amphibians collected or counted during a fish/amphibian kill investigation be positively identified. Every effort should be made to use the skills of a professional herpetologist for the proper identification of both adult and larval amphibians. If there is no herpetologist on staff with the resource agency, local universities or natural history museums may have someone available for such work.

Establishing Monetary Values

Our method used to establish monetary values for U.S. amphibians that are aquatic or breed in aquatic habitats is similar to that used for fishes by the AFS (1982 and 1986). Value was assigned to species based on wholesale prices (*i.e.*, retail price less 40%) given in commercial price lists of amphibian and reptile dealers. Values for some salamanders are from available price lists of wholesale dealers who sold them for fish bait. Normally, we selected the lowest price from the range of prices presented by dealers. We increased values for taxa that have limited distributions or which are rare or endangered. It was felt that these limited resources required additional monetary values because any attempt at mitigation would be more expensive for such species. In all cases the subcommittee attempted to reach a value that would establish fair and equitable compensation (wholesale market values or transaction evidence) if the local resource (amphibian population) were to be destroyed by human activity. For species not listed on available price lists, we derived a value from a similar or closely related species. Though not listed separately, values of larval amphibians should be calculated at a fraction of adult values, such as 2% of the value of an adult. However, the affected larvae need be identified only to genus.

Notice

Monetary values of U.S. amphibians can change according to the fluctuation of the market caused by demand for a certain species or inflation. It is unlikely that the values of these animals will ever decrease.

A Portable Device for Restraining Rattlesnakes in the Field

Field studies of rattlesnakes often require researchers to work alone and on foot in remote areas. Under such conditions, equipment used to handle and restrain rattlesnakes for data collection must be lightweight, durable, and easily transported, as well as safe for both snake and researcher.

A wide variety of devices have been described for restraining unanesthetized venomous snakes. These include squeeze boxes (Quinn and Jones 1974), modified buckets (Gillingham et al. 1983), and transparent tubes (Prestt 1971; King and Duvall 1984). Unfortunately, the first two methods are somewhat cumbersome for field use, and all three considerably restrict the researcher's access to some parts of the snake's body.

Perhaps the oldest type of tool for restraining poisonous snakes is the noose or strap stick (Schmidt and Davis 1941; Conant 1958; Bellairs 1967; Fowler 1978). The loop usually consists of leather, but King and Duvall (1984) use a nylon cord loop in conjunction with their plastic tubes. This sort of tool has received mixed reviews in the past. Ball and Bellairs (1972) drop it from their review of Bellairs' (1967) article, and Conant (1975) fails to mention it in the revised edition of his field guide. Chief criticisms of the strap stick are that the noosed animal may injure itself trying to escape and that it may be difficult to release the snake after examination (Conant 1958).

It is likely that there is no perfect device for immobilizing venomous snakes; each will vary in suitability according to circumstances. We have not tried all the methods described in the literature, but it seemed to us that the strap-stick or noose held promise as a portable field tool if it could be designed suitably. In this note, we describe an adjustable, padded loop (noose) that we believe

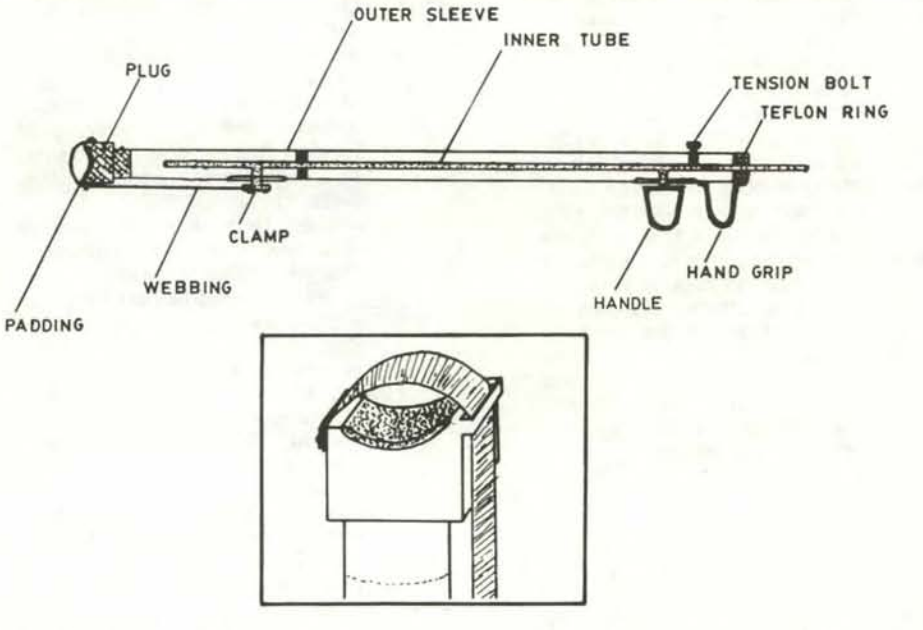

Figure 1. A cut-away view of an adjustable padded device for restraining rattlesnakes (not to scale; in our model the outer tube is about 90cm long and 2.5cm in diameter). Inset: a close up of the device's plug end (fuzzy part of Velcro used).

represents a considerable improvement over traditional strap sticks and nooses to immobilize rattlesnakes (and probably other venomous snakes).

The apparatus is constructed of an outer sleeve of aluminum tubing and a moveable inner aluminum tube (Fig. 1). The inner tube is joined at one end to a clamp and at the other to a sliding handle, both of which project outside the sleeve through longitudinal slits. At the loop end, a 2cm-wide piece of polypropylene webbing (such as that used on backpacks) is anchored to one side of a padded concave plug and is connected to the clamp projecting from the inner tube. The action of the sliding handle tightens the loop over the padded end, resulting in a constriction that is semi-circular rather than circular in cross-section. A bolt threaded through the outer sleeve at the handle end can be tightened against the inner tube to maintain the tension in the noose at the required level. This apparatus can be manufactured for about $15 in material costs by a competent machinist.

The entire apparatus weighs about 480g and can be carried comfortably in one hand along with Pillstrom tongs and meter stick. In our experience, the device will accommodate rattlesnakes of all sizes (350mm-1200mm SVL) except neonates. From a standing position, it is easy to pass the loop over the snake's head and tighten it around the neck directly behind the jaws. The dorsal scutes are held against the padded surface of the plug and the webbing presses against the ventrals. If a snake is particularly aggressive, tongs can be used to direct its head into the loop, but this usually is unnecessary. The semi-circular constriction of the broad webbing distributes the pressure over a large area and does not put undue pressure on the snake's trachea. Once restrained, an excitable snake can be prevented from injuring itself in the loop by steadying its body with a free hand. However, most snakes become quite inactive when restrained. In fact, we found that the only injuries caused by this device occur on large snakes that are frequently recaptured. The skin on the dorsal surface of the neck is sometimes abraded when these snakes struggle as they are stretched out against a meter stick for measurement. These injuries are apparently not serious and, to our knowledge, have not caused the death or disability of any individual.

With this apparatus, the researcher has access to the snake's entire body and one person can palpate for follicles, embryos, or food items with extremely low risk of injury. With practice, the average rattlesnake can be restrained and processed (sexed, measured, rattles counted, palpated, marked, and then released and weighed) within four minutes. Rattlesnakes can bite while in the device, but since the loop is controlled from the opposite end, the possibility of the researcher being bitten is remote. The apparatus can in fact be safely grasped quite close to the snake's head for careful measurement of SVL. One drawback we found was that large snakes (>800mm SVL) could move the apparatus, albeit slowly, if it were simply laid on the ground; therefore, when palpating or marking larger snakes, it is advisable to pin the apparatus against the ground with a knee or leg, which we found easy to do without loosing balance. Snakes are easily released from the loop by loosening the bolt at the handle end. Usually, the loop falls open by itself if the entire device is held vertically; rarely, the loop gets stuck and has to be loosened slightly with a small stick. Overall, this device is durable and trouble-free, although the padding on the plug and the webbing become abraded after many uses and need to be replaced occasionally. Its effectiveness was demonstrated during a three year mark-recapture study, in which approximately 1,700 individual rattlesnakes *(Crotalus viridis)* were marked and about 2,540 recaptures of these snakes were obtained (MacCartney 1985).

NEUTRAL PARAFORMALDEHYDE SOLUTION FOR FIELD USE

Formalin fixatives and concentrates in liquid form are difficult to transport over long distances. It is legally difficult to ship formalin solution in most countries because of its corrosive nature and highly irritating fumes (Busack 1981).

Huheey (1963) modified Taub's (1962) procedure for the use of solid paraformaldehyde as a transportable form of fixative by adding sodium carbonate to counteract the formic acid that is generated. The mixture, however, is significantly alkaline and initiates specimen clearing in a relatively short time (weeks), particularly in hot weather and in specimens (e.g. frogs & geckos) with permeable skins.

I have modified Huheey's method by adding a neutralising system; solutions mixed in this manner have given satisfactory results under field and laboratory conditions for up to two years. As described, the following procedure will make up 2 l of neutralised 10% formalin solution.

In the laboratory prepare the following:

1. Add 21 g citric acid to a small plastic bag and seal;
2. Thoroughly mix 80 g flaked or powdered paraformaldehyde, 20 gm anhydrous sodium carbonate (or hydrated equivalent) and 0.5 g calgon or Pyroneg or other solid form wetting agent, in a larger plastic bag;
3. Place the *sealed* bag of citric acid in the larger bag and seal the larger bag (preferably hermetically);
4. Rebag this kit and seal again as a damage/spillage precaution. Alternatively, pack into a sealable drum (suitable for transporting large quantities of kits). These kits may be stored for at least 6 years without a decline in effectiveness.

In the field, prepare the solution as follows:

Add contents of large plastic bag to 2 l of water while stirring. Flakes dissolve in ca. 4 h (20-30° C) with occasional agitation. This is best done overnight, or several hours before the fixative is required. If the container is sealed, the sloshing caused by vehicular movements is ideal agitation. Initial stirring is necessary with paraformaldehyde powder to prevent sludging and caking of the powders on the bottom of the mixing vessel. Dissolution takes ca. 20 minutes.

When all the paraformaldehyde (flakes or powder) has dissolved, add citric acid and stir occasionally until no more carbon dioxide gas evolves (5 min). *Do not seal container;* allow gas escape for about one day. The neutralised (pH ca. 7) 10% formalin solution is now ready for use.

MODIFICATIONS

The concentration of formaldehyde can be increased or decreased, e.g. for 20% formalin use only one litre of water (the paraformaldehyde will take longer to dissolve); for 5% formalin use four litres of water.

A TECHNIQUE FOR PERMANENTLY MARKING LIZARDS

Long-term population studies frequently use capture-recapture census procedures to estimate the size of populations. These procedures require marking individual animals when they are first captureed so that they can be identified in subsequent recaptures. Heretofore toe clipping has been the only proven method of marking individual lizards for permanent identification. However, toe clipping has significant drawbacks for capture-recapture studies that require frequent censuses and identification of individuals each time they are seen. A toe-clipped animal must be recaptured and handled to be identified, and frequent recaptures disrupt the normal activities of individuals. Lizards may also become "noose shy" and wary of census takers. Hence, as part of a long-term study of the population biology of *Uma inornata,* we developed a marking technique that enables us to identify individuals by resighting rather than recapturing.

Nace and Manders (1982) developed a technique for marking amphibians with colored beads. We modified their technique to mark lizards. The numbers 0 - 9 were assigned to ten different colors of plastic jewelry beads (Paramount Novelties, Los Angeles, California). Three beads (2 mm thick X 2.5 mm in diameter) were sutured through the tail with surgical steel monofilament. The resulting identification mark is about 6 mm long by 2.5 mm wide lying parallel to the long axis of the tail. By using only three beads and ten colors up to 1000 lizards can be given unique marks.

The marks are applied in the field using surgical steel monofilament strands that have been previously prepared in the lab (Fig. 1a). Strands of 15-cm-long 000 monofilament (32 gauge) are twisted around a 20 gauge hypodermic needle to form a loop in one end. Appropriately colored beads can be strung in the field as needed. Note that because the beads are "read" from front to back, the beads must be strung last number first.

A 22-gauge hypodermic needle is pushed through the ventral side of the lizard's tail at a point distal to the male's hemipenis and lateral to avoid the caudal vertebrae. After the monofilament is threaded through the needle from the top (Fig. 1b) the needle is removed leaving the wire, loop, and beads in place. The needle is then passed through the monofilament loop and pushed through the dorsal side of the tail, distal to the first insertion. The wire is threaded through the tip of the needle (Fig. 1c), so that when the needle is removed the end of the wire extends through the loop. The end of the wire is then bent back through the loop, pulled tight, then cut close to the loop leaving the beads securely fastened dorsolaterally to the tail (Fig. 1d). We recommend that the beads be sutured snugly to the surface of the tail to prevent snagging in vegetation. With practice the marking procedure can be accomplished by one person in about five minutes.

Before marking lizards in the field we recommend dissecting preserved specimens to locate the region where the tail autotomizes and to determine the position of the hemipenis, its retractor muscle and lymphatic chamber. Preserved specimens can be used for practice to determine if the method is suitable for species with heavy osteoderms in the tail.

All lizards in our study (572) were toe clipped when first captured and those larger than 6 cm snout-vent length were also marked with beads. A total of 357 lizards was "beaded" from March 1985 to September 1987. None of the lizards lost their beads during this period. A lost mark would have been evident in the capture of a toe-clipped lizard without beads. However, 18 marks (about 5%) required repair, due to the anterior suture pulling through the tail because it was placed too close to the lateral edge.

Some of the marks are known to be more than two years old. To date we have not observed necrosis or tail loss that can be attributed to this technique. Tails of animals marked as juveniles did not exhibit abnormal growth as they grew to adult size.

We have no indication that the beads interfere with the lizards' behavior. Marked males and females have been observed copulating and nearly all adult females have been recorded as gravid during three field seasons of the study.

The cryptic coloration of *U. inornata* probably contributes to its survivorship. We do not have any way of testing the hypothesis that colored beads significantly compromise the cryptic coloration and thus increase mortality. Such a test would require a control population with unmarked individuals that could be recognized. We are not aware of a means to accomplish this with small lizards. However, indirect observations indicate the marks probably do not affect survivorship adversely. Jones and Ferguson (1980), and Simon and Bissinger (1983) tested the effect of different colored paint markings on the survivorship of *Sceloporus undulatus* and *S. jarrovi.* These studies were unable to demonstrate an affect of color on survivorship. We have no a priori reason to believe that the situation would be different for *U. inornata.*

We also have some evidence from the recovery of carcasses in the field. Whereas nearly all adults on the site were beaded only one of eleven shrike kills that we recovered was a marked adult lizard. To our eyes the beads are less obvious than the intense orange breeding colors of both males and females.

We are not aware of any reasons that the beading technique can not be used with other species of lizards. We have marked and resighted *Phrynosoma mcalli* and *Gambelia wislizenii* on our study site and Allison Alberts (University of California, San Diego, Personal Communication) has successfully applied this technique to *Dipsosaurus dorsalis.* Thus, we recommend its use for long-term studies that require frequent recognition of individual animals.

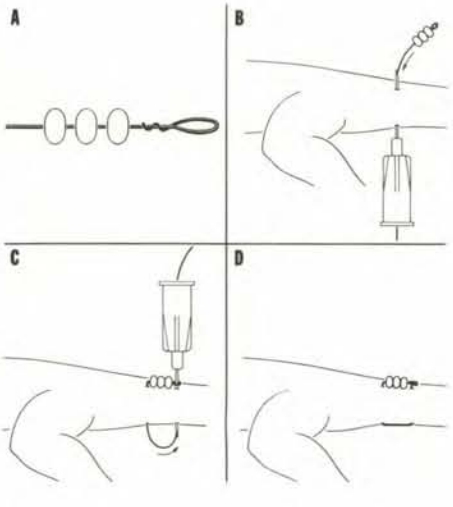

Figure 1. Representative stages in the described technique for marking a lizard with beads. See text for details.

ACKNOWLEDGMENTS

We thank Terry Hicks for discussion of the technique and contribution of materials. Randy Limburg, Dick Durtsche, and Don Bolda provided assistance in the field. Vic Muth assisted with the development of the technique and provided invaluable support for the project. The University of California, Boyd Deep Canyon Desert Research Center provided logistical support and partial funding. This work was also funded by the California Department of Fish and Game (Contracts C816 and C1330) and the US Fish and Wildlife Service.

CORRECTING FOR MAGNIFICATION WHEN TAKING MEASUREMENTS DIRECTLY FROM RADIOGRAPHS

The collection of detailed life history information on turtles has received increased attention in recent years due to a general lack of adequate life history data on the long-lived iteroparous organisms (Wilbur 1975). One area of renewed interest is with turtle reproduction, which has resulted in an increased use of radiography to assess reproductive condition, patterns, and egg size of freshwater species (e.g. Gibbons et al. 1978; Gibbons and Greene 1979; Seigel 1980; Graham 1981; Gibbons 1982, 1983; Kofron and Schreiber 1985; Graham and Forsberg 1986; Turner et al. 1986; Christens and Bider 1987; Congdon et al. 1987). While it has been demonstrated that whole-body exposures of turtles to massive doses of X-irradiation are lethal (Altland et al. 1951; Cosgrove 1965, 1971), there is no empirical evidence to indicate that minimal dosages (such as those reported in this study and others on turtle clutch size) are destructive. Gibbons and Greene (1979) concluded that hatching success and frequency of abnormalities in young from eggs irradiated at 70 kV for 0.7 s at 200 mA were not significantly different from non-irradiated (control) eggs. Most turtle biologists appear to agree that judicious use of X-ray (at the low dosages normally used) provides a non-destructive way to gather data from living animals (such as clutch size) which are otherwise difficult to obtain. In addition, egg dimensions can be precisely determined from radiographs (Gibbons and Greene 1979).

During recent studies of turtle clutch size and egg dimensions (performed at 200 mA and 70 kV for 0.8 s) we noticed that images of turtles and oviducal eggs on radiographs were slightly enlarged. In a sample of 23 Blanding's turtles (*Emydoidea blandingi*), the radiographs of the turtles were enlarged an average of 12.8% (Range = 10.3-15.4%, SD=1.22). The reasons for this image enlargement are quite simple and we believe that researchers should be made aware of this effect and of the ways that it can be compensated for when measurements are taken directly from radiographs.

The degree of image enlargement is directly proportional to the distance between the film and the object being X-rayed. To assess the degree of magnification, a series of radiographs of coins (five-cent pieces) was taken with the coins at various distances from the radiography film using both table-top and bucky-loaded film cassettes. In the table-top procedure, the film cassette is placed directly beneath the object to be radiographed, whereas in the bucky-loaded procedure, the film cassette is positioned in a tray beneath the table surface. The resulting images showed enlargement of coin diameter from 0.9-11.4%. Of the two procedures, we found that the bucky-loaded cassette produced the greatest increase in coin diameter (8.1 and 11.4% at coin-film distances of 8.9 and 13.4 cm respectively). The smallest enlargement error (0.9%) resulted when the table-top film cassette was used and the coin was placed directly on it.

The distance between the X-ray source (focal spot) and the film is usually adjustable and can be varied from application to application. Our focus-to-film distance was 101.6 cm for bucky-load and 92.7 cm for table-top. Both focus-to-film and object-to-film distances are variables which directly influence the extent of image magnification. As long as focus-to-film distance is kept constant, a correction for object-to-film distance can easily be made.

$$\text{Image size} = [\text{OS}] \times [\text{F-f distance}/\text{F-O distance}] = \text{OS}\left[1 + \frac{\text{O-f distance}}{\text{F-O distance}}\right]$$

where [OS] = object size, O = object, F = focal spot, and f = film.

However, unlike coins, our turtles varied in size, which meant a different degree of magnification for each individual. For example, we found that the amount of magnification on radiographs of Blanding's turtles increased by 0.9% for each 10 mm increase in carapace length or 5 mm increase in shell depth. A simple way to correct for magnification would be to place an object of known size (e.g. a coin) on a block of foam beside the animal at the same distance from the film as the anatomical structure to be measured (e.g. the oviducal eggs). A ratio of known object size to the size of the object on the radiograph could then be used to adjust egg dimensions measured directly from that picture.

Another concern about radiographic magnification centers on whether or not turtles are radiographed upright or upside down. Turtles in an upright position would result in less enlargement and greater uniformity of magnification since oviducal eggs would likely lie more on the same plane - just above the plastron. Congdon et al. (1987) indicated that because the X-ray machine they used during 1978-1979 produced photographs that enlarged turtle egg size, they restricted their analysis to data obtained from a new X-ray machine used from 1980-1983. Their statement implies that the newer machine did not enlarge egg images, but we are confident that enlargement will occur with *any* X-ray machine. The data that they did not use might have been salvaged by a correction technique similar to the one we propose. In any case, workers using radiography to determine internal dimensions, such as egg diameter, should consider the caution and correction of magnification reported here.

ACKNOWLEDGMENTS

We thank Francis R. Cook of the National Museum of Natural Sciences in Ottawa for the use of X-ray equipment and facilities that led to our initial discovery of the enlargement problem. We also thank Janet Graham for technical assistance in radiographing coins and for sharing with us her experience with, and knowledge of, radiography.

FISHING FOR "SPRING LIZARDS": A TECHNIQUE FOR COLLECTING BLACKBELLY SALAMANDERS

Salamanders of the genus *Desmognathus* are often important components of lotic ecosystems in the Appalachian region of the United States and, as such, have been the focus of a number of ecological and life history studies (Barbour et al. 1969; Huheey and Brandon 1973; Danstedt 1975; Hall 1977; Tilley 1977, 1980; Hom 1987). The most aquatic members of the genus, however, are some of the least studied because, in part, they are difficult to collect. Blackbelly salamanders, *Desmognathus quadramaculatus,* in particular are fast and elusive, and collecting a large series of them requires a great deal of time and energy (Tilley 1982). Conant (1975) likened collecting this species to ". . .going fishing with your bare hands." Other techniques have been suggested such as the use of flotation-type nets or electrofishing (Hall 1982), but these are often ineffective or expensive.

Considering the difficulties in collecting *D. quadramaculatus,* it is surprising that this is the major salamander species sold as "spring lizards" at bait stores throughout the southern Appalachians. In talking with bait store owners in northeastern Georgia, we learned that salamanders are purchased from local "lizard hunters" in amazing numbers. One store owner told us that she has purchased as many as 300-400 salamanders at a time from a single collector. Moreover, these numbers represent selective sampling of relatively small individuals (50-70 mm SVL) because larger ones are functionally useless as fishbait.

For "lizard hunting" to be cost effective, the collecting technique obviously must be far more efficient than collecting by traditional methods. Because this collecting tool may be valuable for field studies involving this and other salamanders, we present here a description of the technique as well as data on its relative efficiency.

A "fishing pole" is used that is both simple and inexpensive to construct. A short length of fishing line is tied to a loop at the end of a heavy wire ca. 40-50 cm long (the long side of a metal coathanger with a curl at one end is ideal). To the other end of this line is tied a fish hook (size 6 or 8) on which the barb has been flattened and the point has been dulled. The line should be sturdy enough to project 3-5 cm straight out from the end of the wire; we used 10 lb. test nylon line. The hook is baited by sliding it longitudinally through the body of a section of earthworm so that no part of the earthworm hangs freely, to ensure that salamanders will not be able to bite the bait without grasping the metal hook.

Collecting should be done at night when salamanders are easily found by observing their heads protruding from under rocks in the stream or from burrows along the bank. A salamander will generally bite the hook immediately when the bait is placed within 1 or 2 cm of its nose. When the hook is in the salamander's mouth, it should be steadily pulled, not jerked, until the salamander is suspended over an open bucket, at which time it can usually be gently shaken free. The hook is seldom embedded but can easily be backed out of the salamander's mouth by hand if it is. If the salamander drops free before it is over the bucket, it often readily takes the bait again if offered the chance.

We collected series of salamanders using this method and by hand collecting in order to compare capture efficiencies. We collected over 90% of all *D. quadramaculatus* seen using this technique but only a third of those seen when collecting by hand (Table 1).

This collecting technique has a number of advantages over more traditional methods:

1. It is much more efficient, as illustrated in Table 1.

2. It is less physically demanding; turning rocks, necessary for hand collecting, can be extremely laborious.

3. Habitat disturbance is minimal.

4. It is simple and inexpensive.

5. Individual salamanders suffer little trauma as evidenced by escapees' eagerness to take another bait.

6. There are usually several chances to capture a single individual, a rare experience for the hand collector.

7. Salamanders in deep narrow crevices can be readily caught. Such individuals are virtually impossible to catch by hand.

8. Extremely large individuals (100+ mm SVL) are often very difficult to capture by hand but are easily caught using this method.

Although this technique has been used for many years by natives of Appalachia, it has been used only rarely by members of the scientific community. E.D. Brodie, Jr. has used a very similar technique to collect desmognathine salamanders, except he soldered the hook directly to the coathanger and used crane fly larvae as bait (Brodie, pers. comm.). Mount and Schwaner (1970) described a method of fishing for *Phaeognathus* in Alabama. However, salamander collecting using fishing-type techniques has largely been restricted to obtaining such fully aquatic salamanders as *Necturus* and *Siren* (Mount 1975).

Table 1. Efficiencies of techniques for collecting *Desmognathus quadramaculatus.*

	NO. SEEN	NO. CAUGHT	% CAUGHT
Hand Collecting	104	35	33.6
Fishing	174	158	90.8

LIFE HISTORY NOTES

Life History Notes is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which **best** describes the nature of their note (e.g., Reproduction, Longevity, Coloration, Morphology, etc.). Figures are permissible to illustrate any data, but should **replace** words rather than embellish them. The section's intent is to convey information rather than demonstrate prose! Articles submitted to this section will be reviewed and edited prior to acceptance.

Standard format, for this section is as follows: SCIENTIFIC NAME (in caps), COMMON NAME (in parentheses) as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, (Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), KEYWORD (in caps). DATA on the animal (one, or at **most** two, references may be ***briefly*** cited in text—***DO NOT*** include complete literature reviews—use summary articles wherever possible). Place of deposition or intended deposition of specimen(s), and catalog number(s). Then, skip a line and close with SUBMITTED BY (Name(s) in caps, and address(es) in full -- no abbreviations).

(NCN) used for common name = no recognized common name.

Recommended citation for articles appearing in this section is as for Geographic Distribution.

CAUDATA

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). **Feeding.** The feeding habits of *Amphiuma tridactylum*, along with other life history characteristics of this species, are poorly known. Crayfish are presumed to be the primary prey item of *A. tridactylum*. However, it appears that a variety of food items are taken that are dependent on factors such as size of the *Amphiuma*, season, and local prey abundance (see Hamilton 1950. Nat. Hist. Misc. 62:1-3; Chaney 1951. Copeia 10:45-49). Here we give an account of a previously unreported prey item for *A. tridactylum*, the common snapping turtle *(Chelydra serpentina)*.

The *A. tridactylum* (adult female; 523mm SVL, 640mm TL) was collected on 28 February 1988 at 2300h from a ditch located in Hammond, Louisiana, using a wire mesh funnel trap. Examination of stomach contents revealed the remains of a juvenile snapping turtle (50mm est. CL) and several crayfish *(Procambarus* sp.*)*. Twenty-six *Amphiuma* stomachs were examined; no other contained a turtle.

We would like to thank R.A. Seigel for his critical review of this note. The new prey item has been deposited in the amphibian and reptile collection of Southeastern Louisiana University (SLU #766).

Submitted by CLIFFORD L. FONTENOT, JR. and LANCE W. FONTENOT, Department of Biological Sciences, Southeastern Louisiana University, P.O. Box 814, Hammond, LA 70402, USA •

PLETHODON VANDYKEI (Van Dyke's Salamander). **Reproduction.** *Plethodon vandykei* is one of the least-studied species of western salamander, and little is known about its habitat requirements or life history. Recently, Lynch and Wallace (1987. J. Herpetol. 21(4):337-340) described the courtship and spermatophore of *P. vandykei* from the Rocky Mountains, but only a single nest has been found in nature (Noble. 1925. Amer Mus. Novit. 166:1-10). Noble mentioned little pertinent biological information on the clutch.

On 21 May 1988, I found a second nest and eggs of *P. vandykei* near a tributary of Elk Creek, at the north end of Lake Cushman, Mason County, Washington (T23N, R5W, Sec 5, SE 1/4). The nest was located in the moist interstices of a partially rotted log (= decay class 3; Maser et al. 1979. In: Thomas (ed.). USDA For. Serv. Agric. Hnbk. No. 553, pp 78-95). The log, probably a Douglas fir, measured 85cm in diameter and about 5m in length. The nest was situated 9cm from the surface of the log, 30cm from the cut end of the log, about 1.5m above the ground, and about 2m from a small headwater stream. An adult female *P. vandykei* (98mm TL, 53mm SVL, and 2.2g) was found under the same slab, 4cm from the clutch. The egg mass consisted of 7 cream-colored eggs in a grape-like cluster measuring about 17.6mm by 11.8mm. No embryos were evident, suggesting that the eggs had only recently been deposited. The eggs were 5.3mm in diameter, and were covered by a thin jelly coat. The eggs did not appear to be suspended by a string, as mentioned by Noble (1925), but they might have been jarred loose when the slab covering the nest was removed. The temperature of the nest cavity was 11°C, considerably cooler than the outside temperature near the creek (29°C).

The surrounding forest was an old-growth stand of western red cedar *(Thuja plicata)*, Douglas fir *(Pseudotsuga menziesii)*, western hemlock *(Tsuga heterophylla)*, and grand fir *(Abies grandis)*. Some canopy trees had been cut down (including the nest log). Some of the logs had been bucked up, while others remained intact on the forest floor. The understory was composed of western hemlock, salal *(Gaultheria shallon)*, huckleberry *(Vaccinium* sp.*)*, and devil's club *(Oplopanax horridum)*. The forest floor had a thick carpet of moss and herbs. The nest log was located on a 14° slope facing NNE. Nine other *P. vandykei* were found in the stand, of which eight were found in or under large logs near the creek. *P. vandykei* is often associated with seeps and streamside talus (Nussbaum et al. 1983), but none was found in the splash zone of the creek, or the talus seep from which it had originated. Two *Plethodon vehiculum* and two *Rhyacotriton olympicus* were also found in the stand.

P. vandykei is protected in the State of Washington, so a photograph of the adult and egg clutch was deposited in the University of Washington Burke Museum (UWBM 2206).

I thank Keith B. Autry, R. Bruce Bury, and Richard L. Wallace for reviewing the manuscript. Contribution 106 of the Wildlife Habitat Relationships in Western Oregon and Washington Project, USDA Forest Service.

Submitted by LAWRENCE L. C. JONES, USDA Forest Service, Pacific Northwest Research Station, 3625 93rd Ave. SW, Olympia, WA 98502, USA •

PSEUDOEURYCEA BELLI SIERRAOCCIDENTALIS (Pine Oak Salamander). **Habitat.** On 24 June 1987, four *P. b. sierraoccidentalis* were observed at ca. 6km WNW Ocampo, Chihuahua, Mexico, in the Sierra Madre Occidental (VanDevender et al. in Press. SSAR Herp. Review). The salamanders (SVL ca. 70-85mm) were emerging from holes formed by rotted tree roots in a roadcut during a light, drizzling-misty rain in the first hours of dark. Emergence was stimulated by a heavy downpour in late afternoon that was probably the first major storm for the summer monsoon. However, the soil around the holes and the salamanders' skin was not wet, suggesting that the response was to very high humidity rather than moisture penetrating the soil. The only previous specimens of *P. b. sierraoccidentalis* (the type series) collected in September 1964 under logs and rocks in pine-oak woodland near Yecora, Sonora, were not active (Lowe et al. 1968. Los Angeles Co. Mus. Nat. Hist. Contr. Sci. 140:1-11). *Bufo occidentalis* (pine-oak toad) and *Halactophryne tarahumarensis* (Tarahumara barking frog) were also active; male *H. tarahumarensis* were calling.

The regional climax for the elevation is Madrean Pine-Oak Woodland. Oaks are very important at the locality, with *Quercus coccolobifolia* (Encino Verde), *Q. pennivenia* (handbasin or crackleleaf oak), and *Q. scytophylla* (silverleaf oak) as dominants. *Quercus arizonica*

(Arizona oak), *Arbutus arizonica*, *A. xalapensis* (Madronos), are common with occasional *Q. viminea* (willow oak) and *Juniperus deppeana* (alligator bark juniper). Pines in the area include *Pinus durangensis* (Durango pine) and *P. herrerai* (pino chino). The roadcut is on the northwest to southwest sides of a hill with volcanic boulders and deep leaf litter under a dense woodland. The canyon bottom is relatively mesic with abundant *Adiantum capillus-veneris* (southern maidenhair fern) and orchids, with permanent water in sections of the stream and at seeps. *Alnus oblongifolia* (Arizona alder) and *Prunus gentryi* (gentry plum) are common trees in the canyon. The habitat differs from the previous Sonoran locality in higher elevation (1830 versus 1525 m), less rock rubble in the substratum, a northwest-southeast rather than east-west canyon orientation, a smaller stream, and greater dominance by oaks in the woodland.

These secretive animals live in habitats that are difficult to survey, especially during the summer monsoonal activity period. Pine-oak forest or woodland habitat for *P. belli* is more or less continuous at middle to high elevations and in deep barrancas in the Sierra Madre from the disjunct Chihuahuan and Sonoran localities southward through Sinaloa to the nearest known locality for *P. b. belli* in the Sierra de Tepic, Nayarit (Gadow 1905. Proc Zool. Soc. London 1905(2):191-244). Photo vouchers deposited into the University of Arizona Herpetological Collection (UAZ 47824-25PSV).

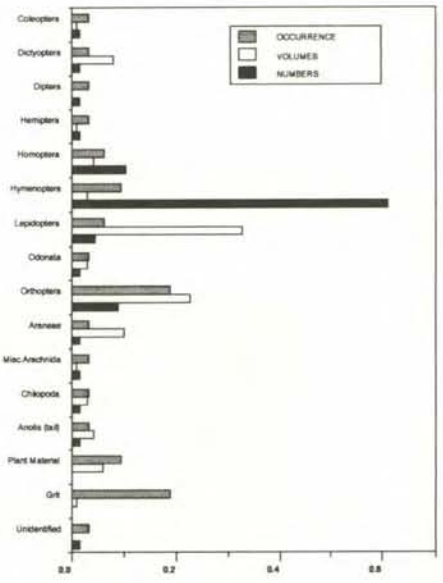
SAURIA

AMEIVA TAENIURA (NCN). **Food Habits.** Prey selection and foraging behavior of this species have not been recorded, although teiids have been described as "intensive foragers" (Regal 1983. *In* Huey, Pianka, and Schoener. Lizard Ecology: Studies of a Model Organism. Harvard). Seven adult lizards (SVL 41-82mm, $\bar{X}$=66.3mm) were collected in coastal coconut palm debris near Paraiso, Provincia de Barahona, Republica Dominicana, on 16 and 17 August 1987 and 10 March 1988. Five of seven were foraging when first seen, two were encountered initially under litter. In addition, ca. 20 other animals were observed but not collected; all but three were moving in a pattern consistent with foraging behavior.

Stomach contents were analyzed and arthropods were identified to order. Volumes of all food were determined using methods of Milstead (1957. Texas J. Sci. 9:410-447). Five of seven specimens contained a total of eleven food items representing five insect orders. In addition, two individuals had (presumably adventitiously) ingested plant materials. Types, numbers, and volumes of food items are given in Table 1.

Table 1. Types, number and volumes (cm³), and frequencies of food items encountered in *Ameiva taeniura* from near Paraiso, Provincia de Barahona, Republica Dominicana (n=7).

Food Item	Nmbr.	Vol.	Freq.
Dictyoptera	4	0.0400	3
Diptera (larvae)	4	0.0350	2
Homoptera	1	0.0025	1
Lepidoptera (larva)	1	0.0050	1
Orthoptera	1	0.0100	2
Plant material	-	0.0450	2
Total	**11**	**0.1375**	**-**



All specimens were deposited in the Bobby Witcher Memorial Collection at Avila College, Kansas City, MO (BWMC 2933-2937 and 3278-3279).

Submitted by **ROBERT POWELL, STEPHEN S. DUER, JOHN S. PARMERLEE, JR.** and **DONALD D. SMITH**, Department of Natural Sciences, Avila College, Kansas City, MO 64145, USA •

ANOLIS WHITEMANI WHITEMANI (NCN). **Food Habits.** Although Williams (1963. Breviora 197:1-8) briefly discussed the ecology of this lizard, food habits have not been recorded. Ten adults, one subadult and one juvenile, all females, were collected on 23 and 28 March 1986, 14 August 1987, and 6 March 1988 from three localities in the Dominican Republic. Though situated in three different biogeographic regions (Henderson and Schwartz. Milwaukee Publ. Mus. Spec. Publ. Biol. Geol. (4):1-70), all sites were xeric, consistent with the description of this species as the most xerophilic in the genus (Schwartz. 1980. J. Herpetol. 14(4):399-406). Sites were on the border between the Llanos de Azua and the Plateau Central (Provincia de Azua, 1km and 3km north of Villarpando, elevation 320m and 370m respectively), characterized by mixed agave-acacia scrub; in the easternmost portion of the Valle de Neiba (Provincia de Barahona, 26km north of Barahona, elevation 200m), dominated by agave scrub; and at the eastern edge of the Llanos de Azua (Provincia de Peravia, 8km west of Bani, elevation 140m), composed of acacia scrub.

Stomach contents were analyzed and arthropods were identified to order. Volumes of all food were determined using methods of Milstead (1957. Texas J. Sci. 9:410-447). No relationships between prey selection or food volumes and size, reproductive condition, or sites of collection were evident. Arthropods were found in all stomachs. Lepidopteran larvae represented the greatest volume (though this was due primarily to two large individuals found in one specimen), ants were present in greatest numbers (41 of 67 total arthropod food items), and orthopterans appeared most frequently (in six stomachs) and also represented the second largest component by volume. In addition, six lizards' stomachs contained grit and three contained plant matter (ingestion of both was presumably adventitious). Further, the largest specimen (SVL 53mm) had ingested the tail of an anoline lizard (probably *A. whitemani* as other species are unlikely sympatrics). Results are summarized in Figure 1.

Figure 1. Relative frequencies of food volumes, numbers, and occurrence in *Anolis w. whitemani* from the Dominican Republic.

These data indicate that prey choice by *A. whitemani* bears a great similarity to that of sympatric Hispaniolan xerophiles in the genera *Leiocephalus* and *Ameiva* (unpublished data). This would indicate that food selection is more dependent on availability (i.e., habitat) than preferences in diet.

Specimens were deposited in the Bobby Witcher Memorial Collection at Avila College, Kansas City, MO (BWMC 03141, 03176, 03236-7, and 03280-03286).

Reptile Cages

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Oderless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how door is inserted.

24" Reptile Cage
24" Wide, 12-1/4" High,
12-1/2" Deep
250 sq. in. Floor Area,
Single Vent $36.95

36" Reptile Cage
36" Wide, 18" High,
19" Deep
580 sq. in. Floor Area,
Double Vent $62.95

NEODESHA
PLASTICS INC

TWIN RIVERS INDUSTRIAL PARK
P.O. BOX 371 - NEODESHA, KS 66757

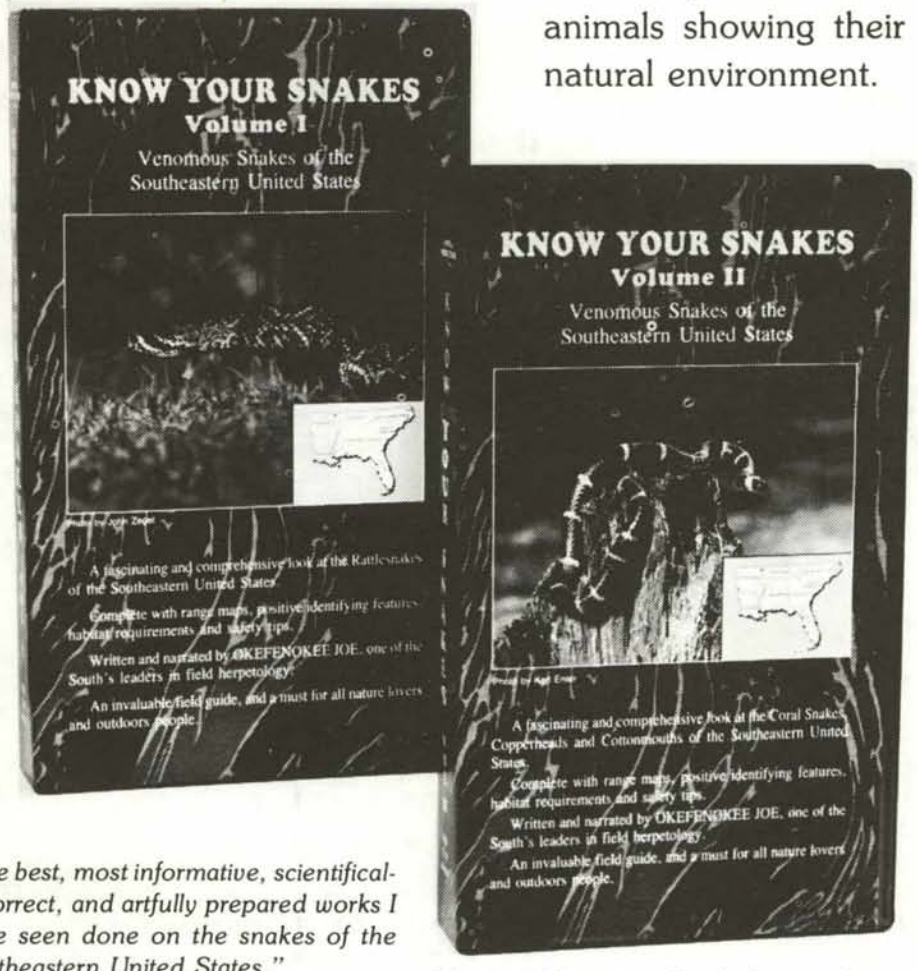
All Features of the 24" and 36" Cages PLUS . . .

- 1/4" Tempered glass by-pass doors with holes drilled for pins or locking
- Aluminum glass track for rigidity and safety for larger reptiles

48" Reptile Cage
48" Wide, 22" High,
21" Deep
920 sq. in. Floor Area,
Double Vent $169.95

72" Reptile Cage
74" Wide, 28" High,
33" Deep
2,200 sq. in. Floor Area,
4 Vents $419.95

As an option we offer dams (litter guards) which are installed at bottom front of cage just behind doors to keep litter from falling in door track when door is opened.



Institutions, dealers, breeders, zoos, and herpotological societies are invited to write on letterhead or call for wholesale and quantity prices.

Prices include all shipping charges in the continental U. S. and are shipped via UPS or commercial truck line.

ATTENTION SNAKE LOVERS!!!

The **first,** the **only** video field guide series of its kind!

Beautiful, authentic full-color footage of these animals showing their lifestyles in their own natural environment.

"I am extremely impressed with the herpetological accuracy, the quality of photography, and the overall presentation of ***Know Your Snakes."***

Dr. J. Whitfield Gibbons
Senior Research Scientist
Savannah River Ecology Lab

"Finally, a video product that provides important basic information and dispels the many myths that surround our local venomous snakes."

Robert M. Lipscomb
Director, Central Florida
Regional Library

"The best, most informative, scientifically correct, and artfully prepared works I have seen done on the snakes of the Southeastern United States."

Maynard Cox
Director, North Florida
Snakebite Treatment Center

"A very informative, first look at snakes for the uninformed amateur naturalist."

R. Howard Hunt

Krieger Brings You the Latest Titles

SNAKES OF THE WORLD

by Kenneth L. Williams & Van Wallach

VOL. I
Synopsis of Snake Generic Names
Orig. Ed. 1989 244 pp. $29.50
ISBN 0-89464-215-4

VOL. II
Synopsis of Living and Extinct Species
Orig. Ed. 1990 Not Set
ISBN 0-89464-216-2

This long awaited work comprises a cross-indexed, alphabetical list of living and fossil generic and subgeneric snake names, including emendations, spelling variations, and errors. Type species designations are provided for all original descriptions. Each name is furnished with its family allocation (if valid) or senior synonym (if invalid), and complete bibliographic references are included. A literature review is presented for controversial names. An invaluable reference for the amateur and professional zoologist, natural history museums and libraries.

Titles In Preparation

LIZARDS OF THE ORIENT, A CHECKLIST

by Kenneth R. G. Welch
Orig. Ed. 1990 Not Set
ISBN 0-89464-327-4

GECKOES

by Herbert Rosler & John Hackworth
Orig. Ed. 1989 Not Set
ISBN 0-89464-365-7

This book is written in a generally scientific way, but gives essential information about geckoes to the amateur reptile fancier as well as the specialist herpetologist. The most important factors here are the biology of the geckoes and their maintenance and reproduction in the vivarium. As well as frequently-kept species, representatives of the rarities of this group of lizards from all five continents will be introduced. Each of the species discussed will be accompanied by a photograph from the Author's extensive collection.

BIOMEDICAL AND SURGICAL ASPECTS OF CAPTIVE REPTILE HUSBANDRY

by Frederic L. Frye
2nd. Ed. 1990 Not Set
ISBN 0-89464-310-X

This second edition is enhanced by the addition of much new and previously unpublished information. Two chapters that are included are written by recognized experts in their fields of interest, Dr. Alex Rubel of Zurich and Dr.Douglas Mader. Dr. Rubel contributed a monograph on radiography and imaging and Dr. Mader wrote a monograph on antibiotic therapy and discusses the relevance of metabolic scaling of anitbiotic dosages. Other chapters include an introduction to herpetology, captive husbandry, a guide to nutrition, infectious diseases, antibiotic therapy, conditions related to the captive environment, radiology and imaging, hematology, non-hemic parasitology, opthalmic disorders, reproductive disorder, developmental anmolies, anesthesiology, surgery, comparative histology, euthansia, necrospy techniques, and pathologic conditions.

When ordering please add $4.00 for first book and $1.00 for each additional to cover shipping charges.

Submitted by **DARLA K. CARR, ROBERT POWELL, JOHN S. PARMERLEE, JR.** Department of Natural Sciences, Avila College, Kansas City, MO 64145, and **DONALD D. SMITH,** Department of Medicine, University of Kansas Medical Center, Kansas City, KS 66103, USA •

CTENOSAURA SIMILIS (Spiny-tailed iguana). **Nest Emergence.** Most members of the subfamily Iguaninae are considered diurnal (Burghardt and Rand 1982. *In*: Burghardt and Rand, eds.; Iguanas of the World, pp. 1-4). Two exceptions to this behavior were reported recently. Mora (1986. Vida Silvestre Neotropical 1:82-83) reported nocturnal activity of nesting female ctenosaurs, and nocturnal nest emergence in hatchling *Iguana iguana* was reported by Drummond and Burghardt (1983. J. Herpetol. 17:290-292).

During a population study of *C. similis* inhabiting the Dr. Rafael Lucas Rodriguez National Wildlife Refuge (Palo Verde), Costa Rica (10°21'N; 85°21'W) some observations were made on nocturnal nest emergence in ctenosaurs.

On 17 May 1984 I observed 14 hatchling ctenosaurs active near nesting sites at night. Others were seen during the next three successive nights. During the following hatching season (May 1985) I captured hatchlings that were moving or asleep near the same nesting sites at night. Individuals actually hatching at night were not observed, but I excavated one nest on 14 May (2200h) and found 18 hatchlings only 2cm from the surface.

An enclosure was constructed at one nesting site in 1986 and 451 hatchlings were captured, most of them hatched at night. In addition, 23 individuals hatching from four different nests outside the enclosure were observed on the nights of 16-20 May 1986. At the same locality some green iguanas were also seen hatching and moving at night. Drummond and Burghardt (1983. op. cit.) pointed out the possibility that nocturnal emergence of green iguanas could be caused or enhanced by the visible presence of an aluminum wall around the nest site. This could also have occurred for hatchling ctenosaurs in this case, but I also observed hatchlings of the two species emerging at night on other nesting sites.

Fitch and Henderson (1978. Univ. Kans. Sci. Bull. 51:483-500) stated that adult ctenosaurs are not active at night or on rainy days, yet several incidents of nocturnal emergence of hatchlings in Palo Verde happened on rainy nights.

M.I. DiMare, J.R. Dixon and T. Qureshi made helpful comments on the manuscript. Financial and logistic support was provided by the Universidad Nacional, Heredia, Costa Rica; World Wildlife Fund; Organization for Tropical Studies (OTS); and the Subdirección de Vida Silvestre of the Ministerio de Agricultura y Gandería of Costa Rica.

Submitted by **JOSE M. MORA,** Rob and Bessie Welder Wildlife Refuge, P.O. Drawer 1400, Sinton, TX 78387, USA •

SERPENTES

BOTHROPS GODMANI (Godman's Viper). **Size.** A male *B. godmani* was found dead on a trail surrounded by cloud forest, Between El Triunfo and Finca Prusia, ca. 2km from El Triunfo, El Municipio de Angel Albino Corzo, Chiapas, Mexico, on 2 April 1988, Mario A. Ramos, collector. The specimen measured 822mm TL and 710mm SVL. The previous maximum recorded length for this species was 789mm TL for a specimen from Honduras (Wilson & Meyer 1982. Milwaukee Publ. Mus. Contrib. Biol. Geol. (6):1-159). The snake, deposited at INIREB's Herpetological Collection (INIRB-0508) exceeds the previous known size record by 33mm. Other *B. godmani* of similar size have been observed at El Triunfo Reserve near the site of collection (A. Thomas, pers. comm.).

Submitted by **MARCO A. LAZCANO-BARRERO** and **ANTONIO MUÑOZ-ALONSO,** Instituto Nacional de Investigaciones Sobre Recursos Bioticos (INIREB), Apdo. Postal 219, San Cristobal de las Casas, Chiapas 29200, Mexico •

MICRUROIDES EURYXANTHUS (Arizona Coral Snake). **Size.** A record length *M. euryxanthus* was collected on 6 August 1983 at 2125h MST on Highway 86 west of Tucson, Pima Co., Arizona by the authors after heavy rains that afternoon. The snake measured 615mm TL, 567mm SVL, was 9.7mm in diameter, and had a mass of 45.8g. The previous record for this species is 551mm TL and 10mm diameter recorded by Gates (1956. Herpetologica 12:155).

The specimen is now being maintained alive in the Animal Resource Center at Arizona State University, Tempe, Arizona, and will be deposited in the University's collection of lower vertebrates upon its death. A photograph of the living snake, showing its TL in March 1987, has been deposited at the Arizona State University Vertebrate Museum (ASU 23511).

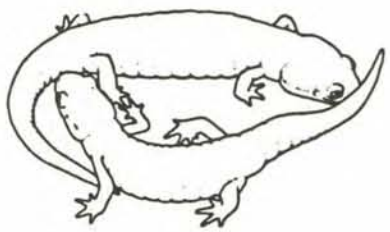
TESTUDINES

EMYDOIDEA BLANDINGI (Blanding's Turtle). **Longevity.** A large (ca. 217mm CL) female *E. blandingi* was collected on 30 July 1988 in Chisago Co., Minnesota (T36N, R21W, Sec 1) with two sets of initials and dates carved into its plastron (Fig. 1). The original initials were carved in the spring of 1926 (O. Larson, pers. comm.) and the second in the spring of 1946 (R. Larson, pers. comm.). There is no distortion in the initials that would be associated with growth. The turtle is assumed to have been mature when first captured in 1926. This turtle was captured in 1982 (East Central Minnesota Post Review, 10 June 1982, page 1) in early June while nesting. This would give the turtle a minimum reproductive period of 56 years (1926-1982).

Gibbons 1987 (BioScience 37:262-269) stated that the average maturity in this species is 15 years. His article also gives the oldest known Blanding's turtle as 48 years. The Chisago Co. turtle exceeds that age by 29 years and is a minimum of 77 years old. The turtle was marked with a Department of Natural Resources tag and released at the capture site.

Submitted by **BRUCE BRECKE,** 217 N. Cedar Lake Rd., Minneapolis, MN 55405, and **JOHN J. MORIARTY,** Minnesota County Biological Survey, Bell Museum, 10 Church St. SE, Minneapolis, MN 55455, USA •

GOPHERUS POLYPHEMUS (Gopher Tortoise). **Mortality.** An adult male *G. polyphemus* (CL 257mm, no discernable annuli) was found dead trapped in an underground chamber. The tortoise was one of 40 we relocated from pine flatwoods at the Windsor Parke develpment site in Duval County, Florida to a reclaimed molybdenum mine site in Clay County, Florida. This particular tortoise was captured 23 July 1987 at the development site, outfitted with a 61g radio transmitter, relocated, and released the same day. When tracked seven days later, it had left the mining site and moved approximately 1.1km south to a previously abandoned gopher tortoise burrow in a sandhill habitat. The transmitter was tracked to this same location regularly for the next twelve months. We saw no signs of activity at the burrow, however, and the odor of rotting flesh was detected.



On 20 August 1988 we excavated the burrow. It was normal in appearance, but only 2m long. Another, discontinuous, tunnel began at the same depth as the end of the first tunnel (ca. 125cm) but approximately 40cm away. The tortoise and transmitter were in a circular chamber, diameter 50cm, discontinuous from the two tunnels, ca. 30 cm from the mouth of the burrow and 25cm deep. The carcass was well preserved and there was no indication of predation. We postulate that the tortoise was at least 125cm underground when the tunnel collapsed, and was burrowing upwards in the direction of the burrow mouth when it became exhausted. Although other relocated tortoises were also tracked, no other mortalities were detected, and we have no reason to believe that this was other than a natural event.

Evidence of natural mortality of adult gopher tortoises is relatively rare, unlike desert tortoises *(Gopherus agassizi)*. W. Auffenberg (pers. comm.) has suggested that armadillos *(Dasypus novemcinctus)* occasionally entomb gopher tortoises when modifying tortoise burrows, but no armadillo sign was detected in this case.

SALAMANDERS OF OHIO

Ralph A. Pfingsten and
Floyd L. Downs, Editors

Ohio Biological Survey Bulletin - New Series
Volume 7 Number 2 1989
ISBN 0-86727-099-3 xx + 315p. + 29Pls.

This publication is the culmination of over 20 years of labor by Ohio's premier herpetologists. Ohio's 25 species of salamanders are described, their distributions and habitats outlined, and their life histories discussed in detail. This monograph also includes identification keys to both adults and larvae, a checklist, chapters concerning education and conservation, a bibliography of over 500 entries, a glossary, and an index. Each species account is headed by a black-and-white photograph of a representative adult of that species. There are 57 numbered black-and-white illustrations, most especially including distribution maps. There are 13 tables. The volume concludes with 29 full-color plates, including photographs of typical salamander habitats, and photographs of salamander life history stages.

There is also a color painting of an adult of every one of the 25 named species of Ohio salamanders, created by David M. Dennis, the Art Editor of SALAMANDERS OF OHIO.

SALAMANDERS OF OHIO sells for $30. Additional separate sets of the 29 color plates are available, and sell for $7. Include 15% of the total costs for postage and handling. Ohio residents add 5 1/2% state sales tax. Orders will be sent by 4th class mail upon receipt of payment. Send check, money order, or purchase order made payable to:

GOPHERUS POLYPHEMUS (Gopher Tortoise). **Food.** Available data on *Gopherus polyphemus* diet are from the northern (Garner and Landers 1981. Proc. Ann. Conf. SE Assoc. Fish Wildl. Agencies 35:120-133) and central (MacDonald 1988. Herpetologica 44:345-353) parts of its geographic range, which extends through the southeastern coastal plain from Louisiana to South Carolina and southward through most of peninsular Florida (Auffenberg and Franz 1982. U.S. Fish Wildl. Serv., Wildl. Res. Rep. 12). *G polyphemus* is thought to serve as a seed dispersal vector for plants (Auffenberg 1969. Tortoise Behavior and Survival. Rand McNally, Chicago), but the capability of seeds to survive passage through its gut has not been demonstrated. We report here on the use of tallowwood fruits *(Ximenia americana)* by the gopher tortoise in the southern portion of its range, and on the ability of the seeds of tallowwood to germinate following ingestion by *G polyphemus*.

The study site is a sand pine scrub in Boca Raton, Palm Beach County, Florida; dense, scrubby oaks (mostly *Quercus geminata, Q. myrtifolia* and *Q. chapmanii*), sand pine *(Pinus clausa)*, and saw palmetto *(Serona repens)* dominate the site. *Ximenia americana*, which grows as a spine-bearing shrub on this site, represented only 0.45% of the shrubby vegetation in over 2,700m of linear transects sampled. *Ximenia americana*, which is toward the northern edge of its range at this site, is a highly polymorphic species with a broad, pantropical distribution (Tomlinson 1980. The Biology of Trees Native to Tropical Florida. Harvard Univ. Print Off.).

We obtained data on the diet of *G. polyphemus* through scat collections and observations. Scats were obtained either during the handling of tortoises or after their deposition. Scat samples collected in September and October of 1987 revealed the presence of large, tan-colored, suboval seeds (14.5-20.0mm in length, 9.0-14.5mm in maximum diameter, and 0.6-1.1mm in seed coat thickness) that matched the appearance of the solitary seeds found in *X. americana* fruit. Thirty-seven percent (13 of 35) seeds from both types of scats collections planted on 30 October 1987 germinated between 30 January and June 1988, confirming the identity of the seeds as those of *X. americana* as well as the ability of those seeds to survive passage through the gut of *G. polyphemus*.

X. americana bears large (ca. 3cm diameter), plum-like fruit that ripens yellow (Tomlinson 1980. op. cit.). Ripe fruits possess a substantial opalescent flesh that has an agreeable odor and a sweet-tart taste; we found most fruits were located within 35cm of the ground. Fruit set was not heavy (i.e., no plant we found had > 12 fruit; see also Tomlinson 1980. op. cit.), but *G. polyphemus* may preferentially select this species: four os seven of the October scat samples obtained directly from tortoises had *X. americana* seeds in them despite the fact that tallowwood represented < 5% of the individuals of species with fleshy fruits eaten by gopher tortoises. MacDonald (1988. op. cit.) found that *G. polyphemus* is selective with respect to most plant species in its diet.

This is the first evidence that *X. americana* fruits are used as food by *G. polyphemus*. *X. americana* ranges to around 30°N latitude in Florida (Little 1978. U.S. Dept. Agric. Misc. Publ. 1361), but workers in northern and central Florida having extensive field experience with *G. polyphemus* have not found evidence of *X. americana* fruits being used as food (J. Diemer and L. MacDonald, pers. comm.). This pattern probably results from the rarity of *X. americana* near the northern limit of its range (Wunderlin 1982. A Guide to the Vascular Plants of Central Florida. Univ. Presses of Florida).

Handling of tortoises was done under Florida Game and Freshwater Fish Commission permit W87107 issued to Ronald Gaby.

Submitted by **MARC P. HAYES, JOSIANE LE CORFF,** Department of Biology, P.O. Box 249118, University of

TRIONYX SPINIFERUS (Spiny Softshell Turtle). **Fecundity.** An unusually large nest of a spiny softshell turtle was discovered 13 June 1988 on a sandbar in the South Platte River, Logan Co., CO. The nest contained 39 eggs of relatively uniform size ($\bar{X}$ mass = 11.324g, SD=0.425g) and appearance. All the eggs were contained within a single nest bowl, and all had white spots of similar size on their uppermost surface. We conclude from these observations that the eggs were laid by a single female, and that this is not an instance of two females depositing their eggs in essentially the same site.

Fitch (1985. Univ. Kans. Mus. Nat. Hist., Misc. Publ. 76) listed 27 as the maximum clutch size for this species, whereas Ernst and Barbour (1972. Turtles of the United States. The University Press of Kentucky, Lexington) reported clutches as large as 32 eggs. Our findings indicate that some individuals of this species may produce clutches of nearly 40 eggs.

RECENT POPULATION CHANGES

This section provides an outlet for anecdotal or minimally documented information on local extinctions or regional population changes. These reports could be valuable historic indications that might enhance our understanding of very long term population trends (in excess of 20 years) and changes in distribution patterns.

Manuscripts should be submitted directly to the editor of this subsection: Ralph W. Axtell, Department of Biological Sciences, Southern Illinois University, Edwardsville, IL 62026, USA.

CHELONOIDES CARBONARIA (Red Footed Tortoise). In the Venezuelan Guayana, *Chelonoides carbonaria* potentially inhabits savannas and forests where there is a marked dry season, whereas *C. denticulata* is a forest species that occurs in areas of high rainfall (greater than 2,000 mm/y). *Chelonoides* are a popular food source for Indians, lumbermen and goldminers (*C. carbonaria* can weigh up to 10 kg and *C. denticulata* can reach 20 kg), and are also a typical dish during Easter week. They are routinely collected by hand and kept in a simple corral until needed. In savanna, hunting consists of burning the vegetation. This clears the terrain and increases visibility, and forces the tortoises to congregate in damp hollows and streams.

Over the past three decades the three principal towns (Ciudad Bolivar, Ciudad Guayana and Upata) have increased their population from less than 50,000 to over 500,000. Demand for *Chelonoides* is apparently no longer met by supply. In spite of a hunting ban imposed in 1974 and extensive control by the National Guard, there is a very intense illegal traffic in tortoises for the two months preceding Easter. Since 1974 the price of a pair of tortoises has increased from Bs 15 to Bs 200 and above. Examination of specimens confiscated by the National Guard indicates that the main hunting pressure is exerted on *C. carbonaria*, and information as to the sources of the contraband and field observations suggest that savanna populations of this species in the northern Estado Bolivar are virtually extinct.

ELEUTHERODACTYLUS JOHNSTONI (Coqui). This frog was apparently introduced from Puerto Rico to Caracas several decades ago. It is very common in residential areas where there are gardens. It is transported passively through the ornamental plant trade and viable populations are now established in Ciudad Bolivar, Ciudad Guayhana, Upata and Guri (Estado Bolivar, Venezuela). There is no evidence that the species has managed to establish itself in natural habitats.

BOOK REVIEWS

Francesco Redi on Vipers, translated and annotated by Peter K. Knoefel. 1988. E. J. Brill, Leiden. xvii+86 pp., 2 figs.

Francesco Redi (1626-1698) first applied scientific method to the study of snake venom and refuted centuries of myth, folklore, and scholarly speculation. In an engrossing and attractive little book, Peter Knoefel makes available to zoologists and medical scientists a translation of Redi's observations on vipers and their venom. As supervisor of the Royal Pharmacy of Ferdinando de Medici, Grand Duke of Tuscany, Redi had access to large numbers of vipers used in preparation of theriac, one of the most valued pharmaceuticals of the time. In his *Osservazioni intorno alle vipere*, he describes the viper venom apparatus and recounts dozens of experiments that show the viper's ability to kill resides in a "yellow liquor" produced in cephalic glands and injected through the fangs. Other experiments show the fluid to be innocuous when given by mouth. Following the conventions of sixteenth century science, he acknowledges the works of earlier authorities dating back to Homer. In passing, he mentions some widely held beliefs about vipers and the treatment of their bites.

A chapter is devoted to the spirited correspondence between Redi and Moyse Charas who termed Redi's "yellow juice" a "simple and quite innocent saliva" and attributed the poisoning to the viper's "irritated spirits helped by the apertures made by the fangs." A third chapter is a brief excerpt from Redi's work on parasitology describing how severed heads of vipers can envenom animals even after many hours, and how viper venom retains toxicity after being dried on broom straws.

A preface gives a brief summary of Redi's life and works. There are 252 explanatory notes keyed to the text but in a separate section. This is a fine piece of scholarship highly recommended for all having an interest in venomous snakes and their venoms.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to rteview herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations and photographs. Manuscripts submitted must be typed, double spaced, on 8.5X11 inch paper, and should be sent in duplicate. We encouerege submissions on Macintosh disks, though we can also work with TEXT (ASCII) files submitted on IBM and compatible floppies. **Herpetological Review** is composed on a Macintosh SE using Microsoft Word, which accepts files from several other word processor applications. Format your documents full-page width; we will fit to **HR** format. Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8X10 inches black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. Herpetological Review will accept commercial advertising. Rates and copy information are available from the advertising manager. Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats. Contact the Managing Editors for details. All ads are accepted at the Editor's discretion.

SSAR ELECTION RESULTS

The results of the 1988 SSAR election are as follows:

President-elect ..... William S. Brown
Secretary .....James S. Jacob
Treasurer ..... Douglas H. Taylor
Board - Regular .....James L. Christiansen
Board - Zoological Parks ... A. Dale Belcher

A total of 543 members voted in this election.

The Society extends its gratitude to the Nominating Committee (George Pisani, Chair) and to the SSAR Elector (Ruth M. Zantzinger) for their hard work, and to the outgoing President and Board Members for their service during their terms.

SSAR COMMITTEES FOR 1988-1989

Following the annual meeting in Ann Arbor, Michigan, President Hugh Quinn appointed the following committees and coordinators for the current year, to report to the Board at the First World Congress of Herpetology, in Canterbury. Individuals with important matters pertaining to the activities of Society committees should contact the relevant committee chair. Addresses for committee chairs are included in the inside rear cover of each issue of *Herpetological Review*.

Conservation: Dale R. Jackson (Ch.), John L. Behler, William E. Cooper, Nat B. Frazer, Tom R. Johnson, Thomas E.S. Langton, and Paul E. Moler.

Grants-in-Herpetology: Darrel Frost (Ch.), Dale Belcher, Arthur C. Echternacht, Thomas H. Fritts, Michael V. Plummer, Hugh R. Quinn, and Eric Rundquist.

Kennedy Student Award: J. Eric Juterbock (Ch.), Robert E. Gatten, Jr., John S. Mecham, Ken R. Marion, and Laurie J. Vitt.

Local Committee Chair: Ian R. Swingland.

Long-range Planning: James L. Christiansen (Ch.), Douglas H. Taylor, James S. Jacob, Henri C. Seibert, Harold A. Dundee, Kraig Adler, Hugh R. Quinn, and George R. Pisani.

Meetings: Henry R. Mushinsky (Ch.), J. Whitfield Gibbons, and James S. Jacob.

Nominating: James B. Murphy (Ch.), Ralph W. Axtell, James S. Jacob, Carl Gans, George R. Pisani, and Robert G. Webb.

Regional Society Liaison: Stephen H. Hammack (Ch.), Fredrick B. Antonio, John J. Moriarty, and Louis W. Porras.

Resolutions: George R. Pisani (Ch.).

Zoo Liaison: Donal Boyer (Ch.), James A. Hitchiner, William W. Lamar, Scott Wheeler, and Ruth Zantzinger.

Common and Scientific Names Coordinator: Joseph T. Collins.

Translations Coordinator: Robert D. Aldridge. ●

AUCTION FOR THE CONSERVATION OF ENDANGERED HERPETOFAUNA FIRST WORLD CONGRESS OF HERPETOLOGY

Proposed by the Fauna & Flora Preservation Society and as part of the social activities, the organisers of the First World Congress of Herpetology have agreed that an auction will be held during the course of the congress, 11-19 September 1989. Books, paintings, carvings, amphibian and reptile films, videos and voice recordings, and herpetological curios, but not live animals, will be auctioned off to the highest bidders. The proceeds of the auction will go towards funding research and management for conservation of the world's endangered herpetofauna, since the Congress is committed to conservation with conservation of species as its main underlying theme.

With his many years' experience as auctioneer at the annual SSAR/HL meetings in the USA, it is anticipated that Joe Collins (Museum of Natural History, University of Kansas, Lawrence) will once again lead the festivities. Proposers of interesting, fundable projects will probably present short summaries to provide breaks and a change of pace as the auction progresses.

It is intended that the highlights of the auction will be listed in the brochure to be circulated in Spring 1989. One is an original watercolour by David Dennis of the Guatemalan beaded lizard (recently discovered and shortly to be described).

The organisation of the auction has fallen upon me, assisted by Mr. Richard Howard, a member of FFPS Council. This is an APPEAL TO ALL HERPETOLOGISTS and others interested in natural history TO DONATE ON BEHALF OF THE WORLD'S ENDANGERED HERPETOFAUNA any surplus items of herpetological interest listed above (amusing or otherwise) that they have in their possession for auctioning-off at the World Congress in 1989.

Please make contact with the Congress Office at the address below to inform them of the items that you intend either to bring or to send in advance so that these are properly listed with the names of the donors:

NEWSNOTES

A PC-DOS PROGRAM FOR PHYLOGENETIC ANALYSIS

Hennig86 is a fully interactive phylogenetic analysis program designed to operate efficiently on inexpensive PC-compatible microcomputers. It requires less than 512K of RAM and needs no math coprocessor or graphics monitor. Being a single .COM file of less than 49K, it can easily be run on a system with no hard disk.

Despite its small size, Hennig86 supports large data sets and provides a wide range of facilities. Up to 180 taxa and 999 characters can be processed. Commands are included for setting the codings and weights of characters, for deleting and restoring characters, and for successive weighting. Trees can be read and saved in symbolic form, rerooted, plotted, and diagnosed. A tree editor, Dos Equis, allows trees to be interactively displayed, diagnosed and modified.

Most parsimonious trees can be calculated by extremely fast approximate methods, by iterative branch-breaking, or by implicit enumeration. The last provides the fastest available method for exact parsimony solutions. According to recent benchmarks by

Platnick (*Cladistics*, 1989) Hennig86's exact calculations are up to 840 times faster than those of its nearest "competitor." Platnick also found that Hennig86 is both faster and more effective than other programs at approximate parsimony calculations.

Tree-calculating commands automatically delete arbitrary resolution and duplicate trees from results. The user never has to wade through listings that turn out to be 100 copies of the same tree. Unlike other available programs, Hennig86 fully supports multifurcating trees in input, output, and diagnosis. Over 10,000 trees can be stored (fewer with larger numbers of taxa), and these can be organized into multiple internal files.

A single-user license for Hennig86 costs $50 plus $5 shipping and handling. ($10 s&h for orders outside U.S. All amounts are in U.S. dollars.) All orders must be prepaid and must specify the user's name (the copies are personalized). Hennig86 may be ordered from:

MEETINGS

LATIN AMERICAN CONGRESS OF ECOLOGY

The First Latin American Congress of Ecology will be held in Montevideo, Uruguay 10-17 December 1989. The meeting is being organized by CIPFE (Centro de Investigación y Promoción Franciscano y Ecológico) and the major sponsor is INTECOL (International Association for Ecology). One of the symposia to be offered during this meeting is "Ecology and Biogeography of Latin American Herpetological Communities." Further information about and registration for this meeting may be obtained from:

Eduardo Gudynas
Coordinador, 1er CLAE
Grupo Ambiente y Desarrollo
CIPFE
Casilla de Correo 13125
Montevideo - Uruguay ●

ALL FLORIDA HERPETOLOGICAL CONFERENCE

The twelfth annual All Florida Herpetological Conference will be held 22 April 1989 at the University of Florida, Gainesville. "International and Florida Herpetological Conservation" will be the theme of the morning session and "Captive Breeding and Maintenance of Herptiles" will be the afternoon theme. A "Workshop for Young Herpetologists" and a dinner/program will be held. The conference is co-sponsored by the Florida Museum of Natural History and the Gainesville Herpetological Society.

Registration and program information is available from:

David Auth
Florida Museum of Natural History
University of Florida
Museum Road
Gainesville, FL 32611, USA

BRITISH HERPETOLOGICAL SOCIETY LONDON MEETINGS 1989

Meetings are held either in the Lecture Theatre of the Linnean Society of London, Burlington House, Piccadilly, London W1 (*), or in the Lecture Theatre of the Zoo Studies Centre, Zoological Society of London, Prince Albert Road (opposite Ormonde Terrace), London NW1 (**). They start at 7:00 pm, ending at 9:00 pm, unless indicated otherwise.

For further details, membership, information on publications and subscriptions to *The Herpetological Journal* and quarterly *BHS Bulletin*, please write to BHS, c/o Zoological Society of London, Regent's Park, London NW1 4RY, UK. As always, SSAR members and herpetologists from other countries are most welcome.

25 April * Mr. Daniel Bennett: Goannas, monitors and other varanid lizards in the world.
23 May * Dr. Christopher Raxworthy: Herpetofauna of the threatened rain forests of Madagascar — a unique habitat.
4 July ** *Amphibia and Reptilia worldwide: their care and breeding.* A discussion organised by the Captive Breeding Committee (Chairman: Mike Linley). Members are encouraged to bring live animals, preserved specimens, amphibian voice recordings and 35 mm colour slides for display and to illustrate discussions.
30 August ** Dr. William Branch (Port Elizabeth Museum, South Africa): Herpetofauna of southern Africa.
2 September ** *Care and breeding of amphibians and reptiles: an open meeting.* Contributions from members — live animal and photographic display. There will be the opportunity for the sale and exchange of members' private home-bred stock. A special Saturday afternoon meeting from 2:00 to 5:30.
10 October ** Dr. David Corke: Lizards in paradise — conservation on St. Lucia (Windward I., Lesser Antilles), West Indies.
29 November ** Dr. Clive Cummins: Effects of acid rain on amphibians.

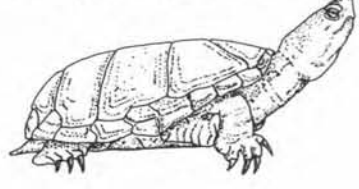
Chairman, British Herpetological Society ●

CONFERENCE ON GLOBAL CLIMATE CHANGE AND LIFE ON EARTH: EVIDENCE, PREDICTIONS, AND POLICY

The Edmund Niles Preserve and Biological Research Station and the New York State Museum have organized a conference on the potential effects of the climate change on natural and manmade systems. Speakers will examine the evidence which suggests that climate change will occur; discuss how changes may affect forests, wildlife, agriculture, disease and parasites, and extinction rates; and consider how policy may need to be changed.

The conference will be held at the New York State Museum, Albany, N.Y. on 24 and 25 April 1989. The conference is cosponsored by the New York State Museum Associates, Albany County Audubon Society, the Behavioral Ecology Group at SUNY-Albany, New York Chapter of the Wildlife Society, the New York Department of Environmental Conservation, the Atmospheric Sciences Research Center of SUNY-Albany, the Roger Tory Peterson Institute, and the Environmental Planning Lobby.

The Honorable Crispin Tickel, Ambassador to the United Nations from Great Britain, will deliver the keynote address.



Speakers include Dr. Daniel Dudek of the Environmental Defense Fund, Dr. Janice Longstreth of ICF-Clement, Drs. Edward Cook and J. T. Overpeck of Lamont Doherty Geological Observatory, Dr. Richard L. Wyman of the E. N. Huyck Preserve and Biological Research Station, Drs. Peter J. Myers and Jan Beyea of the National Audubon Society, Drs. David Steadman and James Clark of the New York State Museum, Dr. Kathy Schneider of the Natural Heritage Foundation and Dr. David Houghton from Woods Hole Research Center. NYS Department of Environmental Conservation's Commissioner Thomas Jorling may participate in policy discussions.

For more information please contact Dr. Richard L. Wyman, Conference Organizer, E. N. Huyck Preserve and Biological Research Station, P.O. Box 188, Rensselaerville, NY 12147, USA (518) 797-3440. ●

SPNHC 4TH ANNUAL MEETING

Society for the Preservation of Natural History Collections will hold its 4th Annual Meeting, 23-28 July 1989, hosted by Tyrrell Museum of Palaeontology, Drumheller and the Biological Sciences Department, University of Calgary. The theme of the meeting is "Collections - Our Treasured Heritage" and will include technical and poster sessions, workshops, tours, a panel discussion, "Public vs. Research Access to Natural History Collections," and a day-long conservation symposium. The meeting is open to anyone with a professional interest in the management and preservation of natural history collections.

A circular, with abstract and registrations forms, was mailed 30 January 1989. Abstract deadline is 15 April 1989. For details contact: SPNHC Conference Secretary, Tyrrell Museum of Palaeontology, P.O. Box 7500, Drumheller, Alberta, Canada T0J 0Y0; Tel: (403) 823-7707; Fax: (403) 823-7131. ●

FEATURES

OOPHAGUS BEHAVIOR IN BROODING PRAIRIE SKINKS, *Eumeces septentrionalis*

Oophagus behavior in brooding lizards has been documented for *Eumeces anthracinus* (Hamilton 1958), *E. callicephalus* (Zweifel 1962), *E. fasciatus* (Cagle 1940; McCauley 1945; Fitch 1954; Vitt and Cooper 1986), *E. inexpectatus* (Hamilton 1958; Vitt and Cooper 1986), *E. laticeps* (Martof 1956; Vitt and Cooper 1985), *E. skiltonianus* (Tanner 1957) and *Ophisaurus attenuatus* (Fitch 1970; Vogt 1981). Many authors have attributed this behavior to hunger (Cagle 1940; Smith 1946; Hamilton 1958; Fitch 1967, 1970; Vitt and Cooper 1986). Although Martof (1956) suggested that this behavior resulted from causes other than hunger, none was specified. McCauley (1945) observed a brooding *E. fasciatus* ingest her eggs after they died. Greene (cited in Groves 1982) observed a brooding *Gerrhonotus liocephalus* remove rotten eggs from her nest, although he did not record if they were ingested. Recent experimental evidence employing brooding *E. fasciatus* suggests that oophagy is initiated by the attending female in order to remove rotten eggs from the clutch (Groves 1982).

During the summer of 1984, two gravid female *E. septentrionalis* were collected in June in Omaha, Nebraska. The skinks were housed separately in 26 x 16 x 13 cm plastic terraria filled with 1.5 cm of moist soil. Fluorescent and incandescent lamps provided a 14L:10D photothermal period. Temperature fluctuated between a high of 34° C during the day to a low of 26° C at night. Skinks were fed crickets (*Acheta domestica*) and mealworms (*Tenebrio moliter*) *ad libitum*; these were dusted with a 50/50 mixture of powdered bonemeal and a vitamin-mineral supplement prior to daily feedings. Drinking water was available in a glass culture dish.

A 15 x 15 cm plate of 0.64 cm thick transparent red acrylic was provided for both terraria. These plates allowed the skinks to be observed while under the shelter.

The two skinks began ovipositing eggs beneath the acrylic plates on 30 June and 8 July. Clutch sizes were 4 and 12, respectively. Toward the end of the incubation period, the following procedures were implemented on four consecutive days. On the first day, one egg in each of the two clutches was killed by destroying the embryonic disk with a needle. On the following day, one rotten egg from a clutch of eggs in another study was added to each clutch. On the third day, one egg in each clutch was heavily swabbed with the inner contents of a rotten egg. Finally, one viable egg from each clutch was removed and exchanged for one in the opposite clutch. All viable eggs were marked with a 6B soft lead pencil for identification. The response of the brooding females to each procedure was recorded on the day following each treatment before a new treatment was initiated. If an egg was missing it was presumed to have been ingested by the attending female.

Within one day following each treatment both females ingested those eggs that were mechanically killed, rotten or swabbed with the contents of a rotten egg. All of the viable eggs, including those from the other female's nest, were successfully brooded to yield healthy hatchlings after incubation periods of 16 (large clutch) and 20 (small clutch) days.

Because the female skinks in this experiment were fed daily until satiated, it seems unlikely that low nutritional status induced oophagy. Observations of *Eumeces* eating apparently viable eggs while brooding (Vitt and Cooper 1985, 1986) may represent species-specific differences in behavior or responses to undetected (by the observers) damaged or dead eggs.

Oophagy may prevent the spread of deleterious microorganisms from dead eggs to viable eggs (Tinkle and Gibbons 1977), and it also may prevent potential predators from finding the nest using olfactory cues (Groves 1982). The results of my observations on oophagy in brooding *E. septentrionalis* are consistent with these hypotheses. More quantitative data are needed to test them critically.

ACKNOWLEDGMENTS

I gratefully thank J.D. Fawcett, H.B. Lillywhite and L.J. Guillette for their comments on this manuscript. Special thanks go to Sam Wurster for his assistance in obtaining skinks for this study.

DEFENSIVE STANCES IN TURTLES

When approached by a potential predator, turtles respond with a variety of defensive posts (Hayes et al. 1988). One such posture, the defensive stance, occurs when the carapace is directed toward an aggressive conspecific or potential predator, thus reducing access to the head and limbs (Dodd and Brodie 1975; Dodd 1978; Hayes et al. 1988). Because turtles occupy a variety of habitats and are preyed upon by many different predators, interspecific variation may be expected to occur in the antipredator behavior of turtles. This study examines presumed defensive stances in a variety of turtle species, and attempts to explain differences between species by differences in ecology and morphology.

I examined the stances of turtles maintained in university, zoo, or nature center collections and in the wild. To elicit posturing, individual turtles were tapped on the anterior, lateral, and posterior margins of the carapace, and the responses were subsequently recorded. I also reviewed the literature on turtles for reports of stances in response to encounters with potential predators or agonistic turtles.

A variety of stances were observed or reported in 22 species comprising 7 of the 14 extant families of turtles (Table 1). The stances of captive turtles observed in this study were essentially the same as those of wild turtles receiving identical stimuli. The various stances are described below.

Frontal Stance. This stance, usually elicited when the front of the carapace was tapped (tactile stimuli) or during the approach of a human (visual stimuli), involved the extension of the rear legs, retraction of the foreparts, and tilting the carapace forward toward the predator. This display was the most commonly observed stance in turtles (91% of the species), perhaps due to the high priority in protecting the head. Biting lunges and hissing also accompanied this stance in some instances. At least two species of turtles used the tail to balance itself while maintaining this stance (Table 1).

Lateral Stance. In response to lateral stimuli, 59% of the species tilted the carapace laterally toward the observer by extending the legs on the opposite side of the shell and retracting the limbs facing the observer.

Rear Stance. When tapped on the rear portion of the carapace most turtles attempted to escape. A few, however, remained stationary (terrestrial species), while 36% of the species responded by extending the forelegs and retracting the posterior extremities. In young *Gopherus agassizii*, this stance was elicited by touching the tortoise anteriorly or placing a finger on the head, and even occurred when unprovoked (Berry 1986). Berry (1986) also noted that the response could be extinguished within a few days by repeatedly touching the tortoise near the head.

The stimuli required to elicit these responses varies among species (Table 1). Although stances were elicited by tactile stimuli in all species of turtles observed in this study, at least three species are reported to exhibit defensive stances when approached by humans (Dodd and Brodie 1975; Dodd 1978; Berry 1986). Of 50 wild *Geochelone elephantopus* approached by a human, none exhibited defensive stances prior to physical contact, suggesting that the display of defensive stances in this species is contingent upon tactile releasers (Hayes et al. 1988).

Interspecific and intraspecific variation occurred between the species in the frequency of stances displayed (Table 2). Because of the small sample sizes and confounding factors involved with captive animals, these differences need to be confirmed by field studies. Nevertheless, the data demonstrate that many captive animals are not completely habituated to aversive stimuli, and species-specific patterns of behavior may be apparent.

The intensity of defensive stances varied between species, apparently due to differences in the morphology and ecology of each species. Aquatic turtles with reduced plastron surfaces (e.g., Chelydridae) exhibited the most distinctive stances (high elevation above substrate, long duration) as well as the most aggressive active defense (i.e., biting). For example, captive *macroclemys temmincki* maintained these displays for periods of 10 sec or longer when touched with a stick and bit the stick whenever possible. Terrestrial turtles (e.g., Testudinidae), apparently relying primarily on their domed carapaces with relatively small external openings for defense, exhibited less distinctive defensive stances (Hayes et al. 1988). The displays exhibited by all *Geochelone* tortoises were short in duration (< 12 sec) and often appeared only after repeated tapping of the carapace. Aquatic

Table 1. Species of turtles for which defensive postures are reported. Nomenclature follows Iverson (1985). Behaviors: 1 = frontal posture; 2 = lateral posture; 3 = rear posture; 4 = tail balancing; 5 = bite accompanying posture. Stimuli: T = tactile; V = visual. Numbers in the source column refer to references in the Literature Cited section. Asterisks indicate observations made in captivity in this study. W refers to species observed in the wild in this study.

turtles with intermediate shell protection (e.g., Emydidae) also lacked distinctive stances; for these turtles, escape into water and hiding are probably the most effective means of predator avoidance. The emydid turtles that I examined always exhibited vigorous escape behavior whether on land or in water; stances were displayed only momentarily (< 2 sec) when turtles were cornered and repeatedly tapped.

Although defensive stances were observed in young (3-8 cm straight carapace length) *Chrysemys picta, Sternotherus odoratus* and *Geochelone pardalis,* none of five young *Trachemys scripta* (3.3-3.6 cm) exhibited stances whereas five adults (ca. 15 cm) did. No discernable size differences occurred in the displays of 23 *Geochelone pardalis* ranging from 3 to ca. 30 cm. Whether these stances represent innate or learned avoidance behaviors remains to be learned.

Since these displays have been observed only in turtles approached or molested by humans and during aggressive encounters with other turtles, it is not known whether these stances are displayed during an encounter with an actual predator. The contexts of previous reports do, however, indicate that these behaviors serve an avoidance function to aversive stimuli, and a defensive purpose is therefore implied.

Dodd and Brodie (1975) suggested that defensive stances in turtles are similar to lateral defensive displays exhibited by many animals in which a particular surface, in this case the carapace, is directed toward a predator, thus reducing access to more vital portions of the body. Defensive posturing, especially if accompanied with hissing, may also serve a deimatic function by exaggerating the apparent size of the turtle and possibly frightening or discouraging potential predators.

This study demonstrates the widespread occurrence of presumably defensive stances in turtles. However, much information is still needed from a variety of species to properly assess the roles of interspecific and intraspecific variation, ontogeny, ecology and morphology in the defensive behavior of turtles.

ACKNOWLEDGMENTS

I thank D.L. Marcellini for permission and assistance in collecting data from turtles at the National Zoological Park in Washington, D.C.; R.A. Nussbaum for encouragement during this study; and W.K. Hayes, M.J. Rosenberg and anonymous reviewers for comments which helped improve this manuscript.

TERMITE NEST INCUBATION OF THE EGGS OF THE MEXICAN COLUBRID SNAKE *Adelphicos quadrivirgatus*

The recent valuable review of formicarial and termitarial incubation of reptile eggs (Riley et al. 1985) reveals records for 33 species of reptiles throughout much of the tropical world. However, for the large tropical areas of México and Central America north of Panamá no records could be found, although several species might be expected to have exploited this niche.

It is therefore of considerable interest that one of us (GPH) discovered three eggs of *Adelphicos q. quadrivirgatus* Jan in a termite nest near El Acuyal, Catemaco, Veracruz, in June, 1984. The eggs were some 10 cm from the surface of a nest 70 cm in diameter, in a "palo mulato" tree (*Bursera cimaruba*), 1.0-1.5 m above ground. The tree was isolated in cultivated fields surrounded by hills covered by semivirgin tropical rain forest. When the tree was felled and the nest broken, hundreds of ants exploited the bonanza of exposed termites, suggesting that reptilian eggs laid in such nests would be liable to ant predation if exposed.

Two eggs failed to hatch, but one hatched almost two weeks after removal from the nest, at the beginning of the rainy season. It is UNAM-LT 3131 of the herpetological collection of the Estación de Biología Tropical Los Tuxtlas. Preserved shortly after hatching, the hatchling's S-V length is 86 mm, tail length 15 mm, and total length 101 mm.

As previously noted (Riley et al. 1985), access to termite nests for oviposition is difficult for most snakes; only small, burrowing species are likely to be successful. *Adelphicos,* with its small, pointed head, smooth scales, and small size, is admirably adapted to exploit termitaria as incubators. It remains to be seen, however, whether the genus as a whole, or even the species *A. quadrivirgatus,* the smallest of the genus, is facultative or largely obligatory in association with termite nests as incubators. We are not aware of any previous records of nests in the genus, nor is the current authority on the genus, Dr. Jonathan Campbell (see Campbell and Ford 1982) (pers. comm.). He also pointed out that the present species is the only representative of the genus inhabiting seasonally dry, lowland forests where termites seem to be more common, whereas the other species occur in the cooler, more mesic uplands.

Another Mexican candidate for formicarial or termitarial incubation of eggs is the lizard *Anelytropsis papillosus* Cope, a blind, legless

PROBABLE INTRODUCTION OF *Lygosoma bowringi* IN ZAMBOANGA CITY, PHILIPPINES

Lygosoma bowringi (following Greer 1977) is widely distributed through southeast Asia and the East Indies. In the Philippines it has been recorded only from islands in the Sulu Archipelago (Taylor 1922; Brown and Alcala 1980). During March 1979 and September 1980, I collected adult and juvenile *L. bowringi* at Ayala Barrio, Zamboanga City, Mindanao (U.S. National Museum of Natural History, Smithsonian Institution) USNM 212623-29, 229483.

Seven *L. bowringi* were collected in ca. one hour over two days, 17-18 March 1979, under, in, and around fallen coconut palm trunks along with *Kaloula picta, Gehyra mutilata, Lipinia quadrivittata* and *Ramphotyphlops braminus* in a small area (ca. 1 ha) of coconut plantation adjacent to a shipyard. In September 1980 at the same site with an equivalent effort, only one *L. bowringi* was collected along with *K. picta* and *R. braminus.*

Areas of identical habitat northwest of Ayala Barrio and northeast of the Port of Zamboanga were surveyed similarly for species of amphibians and reptiles during the same months. No *L. bowringi* were observed at any locality other than the coconut plantation adjacent to the shipyard in Ayala Barrio.

There is a large volume of barter trade between Zamboanga City and the Sulu Islands. Some of the small boats, "bancas," involved in this trade frequent the shipyard at Ayala Barrio. It is likely that *L. bowringi* was introduced into the Ayala area on the bancas and that the specimens collected were descendants of introduced individuals and do not represent a naturally occurring population.

During June 1984 *L. bowringi* was collected in disturbed habitat near Puerto Princesa Airport, Palawan Island, Philippines, by Angel C. Alcala and party (California Academy of Sciences, San Francisco) CAS 157380-81, 157396-400, and 157408-16. Again, it seems likely that *L. bowringi* was introduced into this area by man.

I wish to thank R.I. Crombie, G.R. Zug and R.W. McDiarmid for comments on drafts of this note, and, A.C. Alcala for making me aware of the CAS specimens.

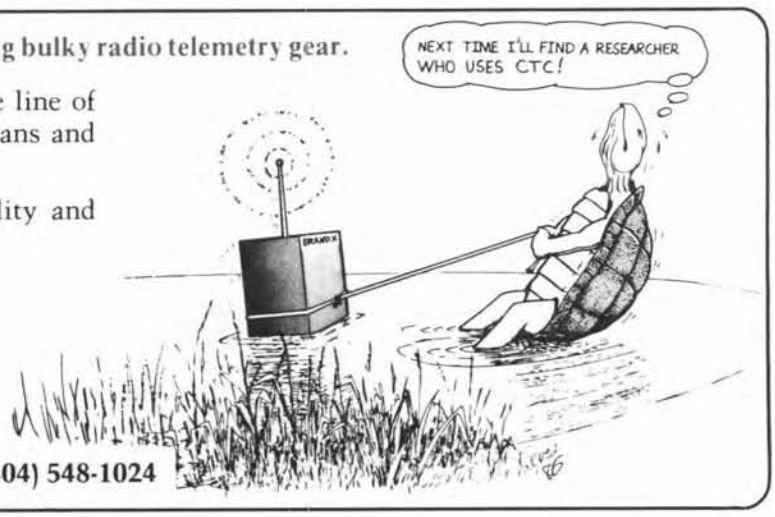
USE OF DIGGER BEE BURROWS BY THE TREE LIZARD (*Urosaurus ornatus*) FOR WINTER RETREATS

Lizards frequently use burrows created by other animals for nocturnal and/or winter retreats. Winter retreats of *U. ornatus* are commonly found underneath bark, in tree stumps, and in granite and limestone crevices, especially near stream courses (Vitt 1974, Worthington and Sabath 1966). Herein, we report the opportunistic use of insect burrows as retreats by *U. ornatus* and the possible thermal benefits.

On 8 March 1987, we observed about 20 active *Urosaurus ornatus* along an eroded stream bank of Alamosa Creek (elev. 6000 ft., T8S, R8W, Section 31, Socorro Co. N.M.). The composition of the bank was silty/sandy sediment and the bank face was uniform and vertical along most of its length with the exception of a three meter section which was pocked with inactive burrows of digger bees (family Anthophoridae). The bank had a predominantly southern exposure and the burrows allowed entrance of at least 15 cm into the sediment. When alarmed, *U. ornatus* quickly escaped into the burrows in addition to retreating into them at nightfall. *U. ornatus* were not observed anywhere else along the bank at this time. About 100 m downstream, the creek entered a steep-walled canyon where no active *U. ornatus* were observed though we noted what seemed to be suitable retreats. Lizards were observed active in both areas two months later.



There is evidence in the literature that *Urosaurus ornatus* do not make the metabolic adjustments that other reptiles make during hibernation. *U. ornatus* do not acclimate to a lower temperature, attempting to maintain the same preferred body temperature throughout the year (Porter 1972). Growth is slowest during the winter season, but specimens have

been observed active, when temperatures allow, year-round (Dunham 1982). Therefore, selection of warmer sites would allow longer activity and more growth. Because of the orientation of the bank and the availability of burrows, *U. ornatus* might gain a thermal advantage by selecting this site as a winter retreat.

To address this question, we compared nighttime temperatures of bank burrows and canyon cracks. Three temperatures were measured in each of 10 burrows, selected randomly from the bank. These were: air temperature, measured 10 cm from the hole; substrate temperature, measured at the burrow opening; and deep temperature, measured 10 cm into the hole. The same measurements were made at 10 cracks selected within the nearby canyon.

Air temperatures were significantly higher at the dirt bank than were those in the canyon ($T=2.636$, $P=0.017$). Deep temperatures were also significantly higher at the bank ($P<0.0001$, Kolmogorov-Smirnov two sample test), but substrate temperatures were not significantly different between the two sites ($T=1.507$, $P=0.149$). These results suggest that lizards in the bank burrows probably were subjected to less severe nocturnal temperatures than would have been experienced in the canyon cracks. Differences between the nighttime thermal environments of the two sites could have contributed to the differences in daytime activity of lizards (active vs. non-active) between the sites. During the evening, the ambient temperature dropped from 6.8° to 2.8° C. and continued to drop throughout the night. Anecdotally, snow was visible in the area, and during the night, heavy frost formed on the ground and a thick layer of ice formed on a bucket of water left in camp.

In addition to receiving more direct and longer duration sunlight during the day, *Urosaurus ornatus* in the bank may have an advantage over those using the canyon cracks, because of a reduced risk of freezing and of shortened warm-up time. Lizards in the dirt bank were seen only within or in close proximity to digger bee burrows, using them for protection from predation, and possibly gaining thermal advantages, thus allowing early spring emergence in relatively harsh conditions.

ACKNOWLEDGMENTS

We would like to thank Howard L. Snell and Randy Jennings for their support and Peter J. Tolson for his comments on the manuscript.

PREDATION BY A CARABID BEETLE ON AUSTRALIAN FROGS

Although there have been many reports of aquatic invertebrates preying on anurans at all stages of their life history (e.g. Savage 1961), there have been few reports of terrestrial arthropods preying on adult frogs (McCormick and Polis 1982). Most of these reports have been based on indirect evidence such as dead or moribund frogs found in the webs or burrows of spiders (e.g. Main & Main 1956; Butler & Main 1959; Groves & Groves 1978), or observations of spiders and mantids eating frogs that they had presumably killed (e.g. McKeown 1952; Nash 1962; Ridpath 1977).

There have been very few observations of arthropods capturing and eating frogs. In Australia there have been observations of the large mantid, *Hierodula werneri*, capturing a green tree frog, *Litoria caerulea*, and then eating it (Ridpath 1977), and of another mantid, *Archimantis latistyla*, eating a live golden bell frog, *Litoria raniformis*. Similarly Littlejohn and Wainer (1978) on two occasions observed the large carabid beetle, *Catadromus lacordairei*, feeding on frogs, first on a live adult spotted marsh frog, *Limnodynastes tasmaniensis*, and second on a freshly dead juvenile brown tree frog, *Litoria ewingi*. In both cases the beetle was found eating the frog and the hunting behaviour was not observed.

During a three year study on the breeding biology of Andersson's toadlet, *Uperoleia laevigata* (formerly referred to as *U. rugosa* by Robertson 1984, 1986a,b, but taxonomically revised by Davies & Littlejohn 1986), I observed another species of carabid beetle, *Chlaenius darlingensis* (body length ca. 17 mm), attacking and eating two species of frogs at a small farm pond 22 km NE of Canberra (35°6' S, 149°19' W). The beetles were

Computerize Your
Field Notes and Collections

GECKO is a computer program for managing field notes and collections.

GECKO will allow you to:

Record genus, species, subspecies, number, locality, county, state, collector or observer, collection number and comments. Family, order and class are entered automatically.

Extract data for viewing, editing or printing by any combination of the above, e.g. iguanid lizard localities for Inyo Co, CA or all herps seen in Texas from June through August.

List data by order of entry, by date or phylogenetically.

Copy selected records to files for use with spreadsheets, word processors or data base programs.

Count number of species for all or part of the data base, e.g. number of species for 1988 or number of species of *Hyla*.

GECKO is very powerful, yet uses simple screen menus. It incorporates a master species list and is sold with your choice of the U.S. and Canadian list of herps, birds or mammals. Other species lists can be purchased separately and merged into a comprehensive list of terrestrial vertebrates. Lists can be easily edited to accommodate taxonomic changes or new species.

GECKO runs on IBM PCs and compatibles with 320K RAM and DOS 2.0 or later. $75 + $3 shipping. California residents add 6% tax. Please specify species list to be included. Additional lists are $25 each. Similar programs which use common names are available for all terrestrial vertebrates.

Sandpiper Software 153 Michele Circle, Novato, CA 94947

often observed systematically searching the bare mud around the margin of the pond with a sinusoidal walk pattern between the water's edge and vegetation (Fig. 1). On 15 December 1980, many recently metamorphosed juveniles of *Uperoleia laevigata* (total length ca. 22 mm) were emerging from the pond, and I observed two being found and attacked by two searching beetles. Similarly, on 19 December 1980, 5 February 1981, and 26 November 1985, I observed calling adult male ground frogs, *Ranidella signifera* (body length ca. 25 mm), being found and attacked by a searching beetle. The search and attack pattern was the same in all four cases. Upon encountering a frog the beetle immediately clasped it and began eating through the body wall. The frogs were apparently unable to detach from the beetle, though they struggled, jumped and attempted to escape. Within a few minutes of being attacked the frogs died, presumably through loss of blood or because the beetle attacked a vital organ. The beetles continued to eat until most of the fleshy parts and the viscera were consumed. Solitary nonvenomous arthropods usually attack smaller vertebrate prey (McCormick and Polis 1982), but in all cases *Chaenius darlingensis* attacked larger frogs, presumably because they were not dangerous prey and could be killed rapidly by the beetle.

Adult males of the leptodactylid frogs, *Ranidella signifera* and *R. parinsignifera*, commonly call in the region that the beetles systematically search and hence are the most likely prey. However, the juveniles of all the species of frogs in the area are vulnerable to this beetle because emerging metamorphosed juveniles must pass through the patrolled region. It is thus likely that this beetle is a significant anuran predator.

ACKNOWLEDGMENTS

I thank Dr. Barry P. Moore, Division of Entomology, C.S.I.R.O., Canberra for identifying the beetle, and Annika Roos for the drawing.

THE PATRONYM AND TYPE-LOCALITY OF *Pelophilus (Epicrates) fordii* GÜNTHER 1861 OF HISPANIOLA

Type-locality restrictions have no legal standing in zoological nomenclature; however, they are important for historical purposes and necessary for designating nominate subspecies. Recently, Wetherbee (1987) restricted the type-localities of *Epicrates fordii* Günther 1861, *Hypsirhynchus ferox* Günther 1858, and *Anolis semilineatus* Cope 1864 to República Dominicana, correcting restrictions of other authors. The new restrictions were made on the rationale that Auguste Sallé almost certainly was the collector of the type-specimens, and that Sallé was never in Haiti, the locality of previous restrictions.

The new restrictions were made based on a comprehensive study (Wetherbee 1985 and 1986) of the history of zoology in Haiti and República Dominicana. Although the patronym given by Günther for *E. fordii* was mysterious, I was confident that no collector named Ford ever worked on Hispaniola, where this species is endemic. Confirmation of that conviction has since been kindly furnished (pers. comm.) by A. F. Stimson of the British Museum: the patronym was for George H. Ford, illustrator of the plate accompanying the original description. Ford was a well known 19th century biological illustrator. This information removes any reasonable doubt that Sallé was the collector and my type-locality restrictions for the above taxa remain unchallenged.

HERPETOLOGICAL HUSBANDRY

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include obser-

vations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

SEX DETERMINATION AND CLINICAL EXAMINATION IN REPTILES USING ENDOSCOPY

It is not possible to confirm the sex in many monomorphic reptiles with traditional methods like weighing, probing the hemipenis cavities or analysing the serum testosterone and estrogen values (Honegger 1978, Wallach and Boever 1983, Hitz 1984, Schildger and Wicker 1987).

Our purpose was to develop an accurate and reliable method of determining the sex of reptiles of the genera *Trachydosaurus, Tiliqua, Egernia, Corucia, Heloderma* and *Varanus*. To become familiar with the internal anatomy, we first dissected dead animals of these genera. We determined that males and females possess hemipenis cavities of similar depth, explaining why the probing of hemipenis cavities is unreliable (Figs. 1 and 2).

Eighty-six randomly selected live animals of various species were sexed by endoscopy (Table 1). This method is described in detail by Schildger and Wicker (1987). After subcutaneous local anaesthesia with 0.1 ml Lidocain 1%, the animal is placed in right facing position. The skin is incised and the intercostal muscles perforated with a blunt medical probe of 1.5 mm diameter. Filtered air (Millipore VCWP 100nm) is insufflated through a

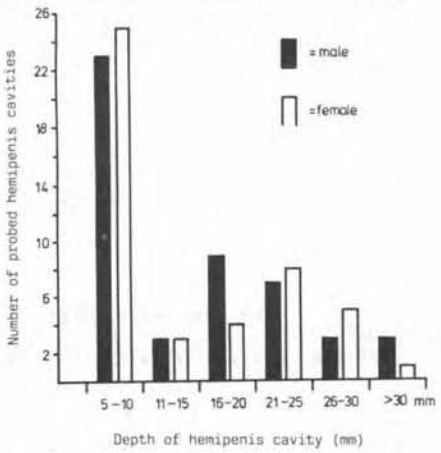

Figure 1. Depth of hemipenis cavities by probing in *Trachydosaurus rugosus.* (Male: Female = 24:25, as determined by endoscopy.)

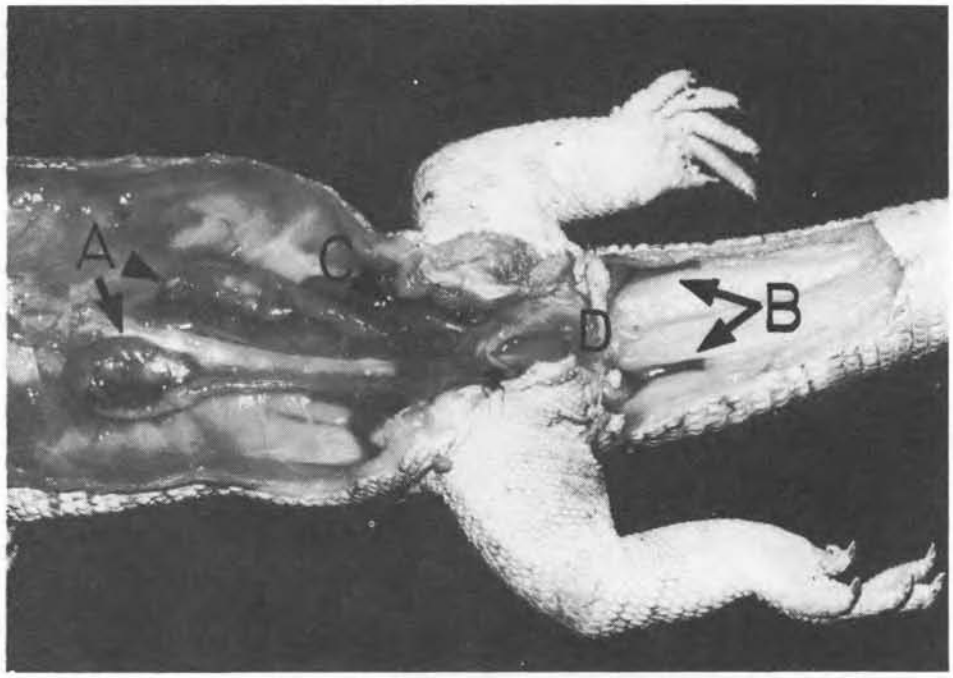

Figure 2. Female *Trachydosaurus rugosus.* A = ovaries. B = hemipenis cavities. C = rectum. D = cloaca.

blunt-ended needle and the endoscope is inserted. The intestines are pressed down by the resulting gas vesicle on the dorsal side. Because the gonads are attached dorsally, near the vertebral column, we now could inspect them through the endoscope which is built like a human arthroscope of 2.7 mm diameter. After endoscopy an antibiotic (Tetracycline 20 mg/ml) is instilled and the incision is closed by adhesive tape. No incidents occurred during or after the operations.

Using endoscopy we estimated the stage of sexual maturity in female animals. Both ovaries of juvenile females were of small size, light yellow color and with small bumps. The ovaries of adult females were large, yellow-reddish and with follicles of different sizes (Fig. 3a). The testicles were oval, yellow and covered with distinct blood vessels (Fig. 3b). In *Corucia*, both ovaries and testicles were of more whitish appearance. In *Varanus* the gonads were covered with black pigmented serosa.

Additionally, we used endoscopy to clinically examine the internal organs: lungs, liver, spleen, intestines and kidneys. As part of a complete clinical examination, we endoscoped dimorphic species of the genera *Dipsosaurus, Physignatus, Amphibolurus, Uromastix, Cordylus, Rhinoclemys* and *Testudo.* In four cases we diagnosed enteritis. In one case each we detected multiple abscesses on the intestinal serosa, an inner mycotic infection close to the ovaries and a scar formation on the liver surface which is typical for a chronic amoebiasis.

Reliable sexing of reptiles is the major prerequisite and a most important factor in captive breeding programs (Wallach and Boever 1983). Endoscopy is gaining importance as a method of clinical examination and we also recommend its use in determining gender in reptiles, when performed by qualified individuals.

Notice Concerning Registration Packets
1st World Congress of Herpetology

We have received word that some colleagues have not yet received their Registration Packets, containing:

1. *Registration Circular* (detailing all Congress events: program, excursions and tours, social events, deadlines, and costs).
2. *Official Registration Form.*
3. *Booking Form* for tours and hotels.
4. *Abstract Form* for spoken and poster papers.

These packets were mailed beginning last Summer, but there have been disruptions in the British postal service during this time.

Accordingly, those who need packets should request them from:

In The Eastern Hemisphere: Dr. Ian R. Swingland, Ecology Research Group, Rutherford College, University of Kent, Canterbury, Kent CT2 7NY, UK (or Telex 965449).

In The Western Hemisphere: Prof. Kraig Adler, Section of Neurobiology and Behavior, Mudd Hall, Cornell University, Ithaca, NY 14853, USA (or Telex WUI 6713054).

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records have a **standard format**, and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full -- no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged). Photographs may substitute for a preserved specimen only when the live specimen could not be collected (*e.g.*, it was a protected species or it was found in a protected area). Photographs must be deposited in a university or museum collection, and the catalog number(s)

Please submit new geographic distribution records, in the standard format only, to Alvin L. Braswell, North Carolina State Museum of Natural Sciences, P.O. Box 27647, Raleigh, North Carolina 27611-7647, USA. Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10 (1):1.

(NCN) = no recognized common name.

CAUDATA

AMBYSTOMA TALPOIDEUM (Mole Salamander) USA: ARKANSAS: Greene Co. 4.5km N Craighead Co. line (T16N, R5E,S22). 24 January 1988. W.E. Meshaka. Verified by S.E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 9562-9568). This new county record marks the fourth known Location of *A. talpoideum* in Arkansas (Meshaka and McLarty 1988. SSAR Herp. Review 19(1):17).

Submitted by **W.E. MESHAKA, B.P. BUTTERFIELD,** Department of Biological Sciences, Arkansas State University, State University, AR 72467, and **R.L. COX,** College of Nursing and Health Professions, Arkansas State University, State University, AR 72467, USA •

AMBYSTOMA TEXANUM (Smallmouth Salamander). USA: ARKANSAS: Izard Co: 2km E Oxford (T18N, R9W, S1). 28 February 1988; .25 km N Oxford (T18N, R9W, S11). 6 March 1988. C.D. Cochran, B. G. Cochran, B. R. McCollum, and M. D. Fletcher. Verified by S. E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 9863, 9864, 10052). New county record; extends range further into the Ozark Mts. (60 km west)(Dellinger and Black 1938. Occ. Pap. Arkansas Mus. 1:1-47; Dowling 1957. Occ. Pap. Arkansas Mus. 3:1-51; Johnson 1987. The Amphibians and Reptiles of Missouri. Missouri Dept. of Conservation).

ANEIDES FERREUS (Clouded Salamander). USA: CALIFORNIA: Trinity Co.: 9.3km N, 5.3km W Big Bar, 1158m. 16 November 1982. M. G. Raphael and L. L. C. Jones. Verified by D. Wake and S. Busack. Department of Forestry and Resource Management, University of California, Berkeley (MGR 193-194). Brown (1948, Copeia (2):136) and Stebbins (1951. Amphibians of Western North America. Univ. of Calif. Press, 539 pp.) reported *A. ferreus* from Trinity Co., but Bury (1970, J. Herpetol. 4(3-4):165-178) could find no museum specimens to document these records; he collected two specimens (MVZ 86968-69) at 4.2km E Salyer, Trinity Co. Our record extends the range 20km E (Bury op. cit.), representing the easternmost locality in California.

Submitted by **LAWRENCE L. C. JONES** and **MARTIN G. RAPHAEL,** Department of Forestry and Resource Management, University of California, Berkeley, CA 94720, USA present addresses: (LLCJ) Forestry Sciences Laboratory, 3625 -93rd Avenue SW, Olympia, WA 98502, USA; (MGR) Rocky Mountain Forest and Range Experiment Station, 222 South 22nd Street, Laramie, WY 82070, USA •

PLETHODON CINEREUS (Redback Salamander). USA: MAINE: Isles of Shoals, Appledore Island (42°59'N, 70°37'W). 12 September 1987. E. Lyman. Verified by J. Taylor. University of New Hampshire Vertebrate Collection (8000-8005). First record of an amphibian on the Isles of Shoals (Borror 1982. Checklist of Flora and Fauna. Shoals Marine Laboratory, Cornell University/University of New Hampshire. 44pp.) All specimens were redback phase.

Submitted by **JAMES TAYLOR,** Department of Zoology, University of New Hampshire, Durham, NH 03824, USA •

SIREN INTERMEDIA NETTINGI (Western Lesser Siren) USA: ILLINOIS: St. Clair Co.: near New Athens 0.4km SW new Hwy 13 bridge, W bank Kaskaskia River (revegetated dredged material disposal area). 3 September 1987. Leo G. Nico. Verified by M. A. Morris. Illinois Natural History Survey (INHS 10764). First record for lower Kaskaskia River, second for county (original record not supported by museum specimen; Hurter 1911. Herpetology of Missouri. St. Louis Acad. Sci. Trans. 20(5):59-274).

ANURA

RANA CATESBEIANA (Bullfrog). USA: TEXAS: Van Zandt Co: County Road 2908 crossing at Purtis Creek, 20 km SSW of Canton. 14 May 1987. D.J. Green and D.J. Thomas. Verified by J.R. Dixon. Texas A&M University (TCWC 66166). New county record (Dixon 1987. Amphibians and Reptiles of Texas, Texas A&M Univ. Press, College Station, Texas. 434 pp.).

Submitted by **DEREK GREEN** and **DAVID THOMAS,** Espey, Huston & Associates, Inc., PO Box 519, Austin, TX 78767, USA•

RANA C. CLAMITANS (Bronze Frog). USA: TEXAS: Camp Co: Unnamed county road crossing at Ellison Branch Creek, 7 km SW of Pittsburg. 28 April 1987. D.J. Green and D.J. Thomas. Verified by J.R. Dixon. Texas A&M University (TCWC 66167). New county record, fills hiatus among Wood, Upshur, and Morris counties (Dixon 1987. Amphibians and Reptiles of Texas, Texas

A&M Univ. Press, College Station, Texas. 434 pp.).

Submitted by **DEREK GREEN** and **DAVID THOMAS**, Espey, Huston & Associates, Inc., PO Box 519, Austin, TX 78767, USA•

SCAPHIOPUS BOMBIFRONS (Plains Spadefoot). USA: ARKANSAS; Conway Co.: 1.8 km SE Morrilton (T6N, R16W, S33). 2 April 1988. S.E. Trauth. Verified by S.E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 10396). New county record and second record for the state. Extends range 30 km E of other locality within the Arkansas River floodplain (Plummer and Turnipseed 1982. Geographic Distribution: *Scaphiopus bombifrons*. SSAR Herp. Review 13:80).

Submitted by **STANLEY E. TRAUTH, BRIAN P. BUTTERFIELD,** and **WALTER E. MESHAKA, JR.,** Department of Biological Sciences, Arkansas State University, State University, AR 72467, USA •

SAURIA

ANADIA PAMPLONENSIS (Lagartija Altiandina de Tamá) (NCN). VENEZUELA: ESTADO TACHIRA: Distrito Junin: Villa Páez, region de Tamá. May 1976. Julio Barbera and Abdem R. Lancini. Verified by J. E. Garcia Pérez. Museo de Ciencias Naturales de Caracas, Venezuela (MCNC 6504, 6518). First record for Venezuela and the easternmost locality for the species, ca. 25km ENE from type locality. *A. pamplonensis* was previously known only from Colombian localities in the Cordillera Oriental de Colombia. The extension of the distribution is not surprising, since the new locality record lies on the Venezuelan spur of this Andean Cordillera. The two specimens generally agree with the descriptions provided by Dunn (1944. The lizard genera *Anadia* and *Ptychoglossus* in Colombia. Caldasia 3(11):63-68) and Harris and Ayala (1987. A new *Anadia* (Sauria: Teiidae) from Colombia and restoration of *Anadia pamplonensis* Dunn to specific status. Herpetologica 43(2):182-190). However, they may differ from the specimens reported by Harris and Ayala (op. cit.) in that the innermost femoral pores are located on the first scale of the most proximal portion of the thigh, instead of being located "preanally" (= precloacal pores?).

We thank Dr. A. R. Lancini and Lic. Pedro Delgado (MCNC) for loan of specimens under their care and Prof. Pascual Soriano for provision of working space in the Grupo de Ecologia Animal of the Universidad de Los Andes, Mérida.

Submitted by **JUAN ELIAS GARCIA PEREZ**, Departamento de Biologia Facultad de Ciencias, Universidad de Los Andes, Mérida 5101, Venezuela, and **ENRIQUE LA MARCA**, Facultad de Ciencias Forestales, Escuela de Geografia, (Area de Biogeografia), Universidad de Los Andes, Apartado 116, Mérida 5101-A, Venezuela•

ANNIELLA P. PULCHRA (Silvery Legless Lizard). USA: CALIFORNIA: Los Angeles Co., 6.4 km SSW Lancaster. 28 march 1988. David A. Mullen. Verified by Lawrence E. Hunt.University of California, Santa Barbara Vertebrate Museum (RCSBVM 21272-21274). Juvenile specimen observed but released 7.2 km W Lancaster, Mira Loma Detention Facility. 22 January 1988. Previously not known from desert floor of Antelope Valley. Probably represents eastern limit of this species range in the region as climatic conditions rapidly become limiting to the east in the Mojave Desert. Extends range 30 km N nearest recorded locality 8 km WSW Acton in Soledad Canyon Los Angeles County Museum.

Submitted by **DAVID A. MULLEN,** Senior Wildlife Biologist, EIP Associates, 150 Spear Street, Suite 1500, San Francisco, CA 94105, USA •

ANOLIS W. WHITEMANI (NCN). REPUBLICA DOMINICANA: AZUA: 1km and 3km NW Villarpando in xeric agave/acacia scrub along HW 2 (elev. 320m and 370m resp.). 12 March 1988. D. D. Smith, P. Ward, R. Powell, and J. S. Parmerlee, Jr. Verified by R. Powell. Bobby Witcher Memorial Collection, Avila College (BWMC 3236-7). These represent the first records from the Valle de San Juan, a different biogeographic region ca. 40km NW nearest previously-described locality in the Llanos de Azua (Schwartz and Henderson 1988. West Indian Amphibians and Reptiles: A Checklist. Milwaukee Publ. Mus. Contr. Biol. Geol. 74:1-264). Schwartz (1980. Variation in Hispaniolan *Anolis whitemani* Williams. J. Herpetol. 14(4):399-406) discussed discontinuities in the range of the species and their systematic implications. Assignment of these specimens to the nominate subspecies supports an association with the proximate populations to the southwest, rather than Haitian populations via the Plateau Central. The Valle de San Juan is more mesic than the remainder of the recorded range, but hillsides overlooking the valley floor provide, at least intermittently, suitable habitat for this xeric-adapted species. The most evident sympatric forms were *Ameiva lineolata* and *Leiocephalus semilineatus*, both noted xerophiles. It appears that these three species share very similar distributional patterns on Hispaniola.

Submitted by **ROBERT POWELL, JOHN S. PARMERLEE, JR.,** and **PAUL WARD,** Department of Natural Sciences, Avila College, Kansas City, MO 64145 USA, and **DONALD G. SMITH,** Department of Medicine 4035B, University of Kansas Medical Center, Kansas City, KS 66103 USA •

CNEMIDOPHORUS SEXLINEATUS (Racerunner). USA: TEXAS: Dimmit Co: 2.2 km W jct 2644 and State Hwy 277. 13-14 May 1988. J.M. Walker, J.E. Cordes and R.M. Abuhteba. Verified by J.M. Walker and J.E. Cordes. University of Arkansas, Department of Zoology (UADZ 2997-3012 & 3014-3021). New county record (Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, 434 pp.) filling hiatus between Webb, LaSalle and Maverick counties. Specimens collected under authority of Texas Parks and Wildlife permit no. 61.

SONORA SEMIANNULATA (Ground Snake). MEXICO: BAJA CALIFORNIA NORTE: 8.5km E (by Mexican Highway 3) of Valle de Trinidad. 7 February 1987. V. M. Velazquez and L. Lee Grismer. Verified by L. Lee Grismer. Hospital Militar de La Paz, Baja California Sur, Mexico (HMLP 2122). This specimen bridges a gap of nearly 130km in northern Baja California between desert and coastal populations in an area where its occurrence was questioned (Frost 1983. Cat. Amer. Amph. Rept. 333.1-333.4).

Submitted by **L. LEE GRISMER**, Department of Biology, San Diego State University, San Diego, CA 92182, USA •

STORERIA OCCIPITOMACULATA (Redbelly Snake). USA: NEBRASKA: Dawson Co.: 3km S, 2km E of Gothenburg. 31 August 1987 (Kearney State College 423, 424). 29 September 1987 [University of Nebraska at Lincoln (UNL 9290)]. Mark M. Peyton. Verified by C. True and J. Lynch. A total of 17 specimens were collected along a 2km stretch of a drainage ditch bank along the Platte River S of Gothenburg during the summer of 1987 and spring of 1988. Collins (1982. Amphibians and Reptiles in Kansas. Univ. Kansas Mus. Nat. Hist., Public Education Ser., 8:1-356) rejected records of *S. occipitomaculata* in western Kansas as being too far west of their range. The presence of a single specimen collected southwest of Kearney, Nebraska (Kearney State College Herptile Collection #161) in 1967, and now these specimens collected 100km W of Kearney may validate those Kansas records. The specimens collected most closely resemble the description of *S. o. pahasape* given by Stebbins (1966. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston), which are found in the Black Hills of South Dakota 640km NW of this collection site.

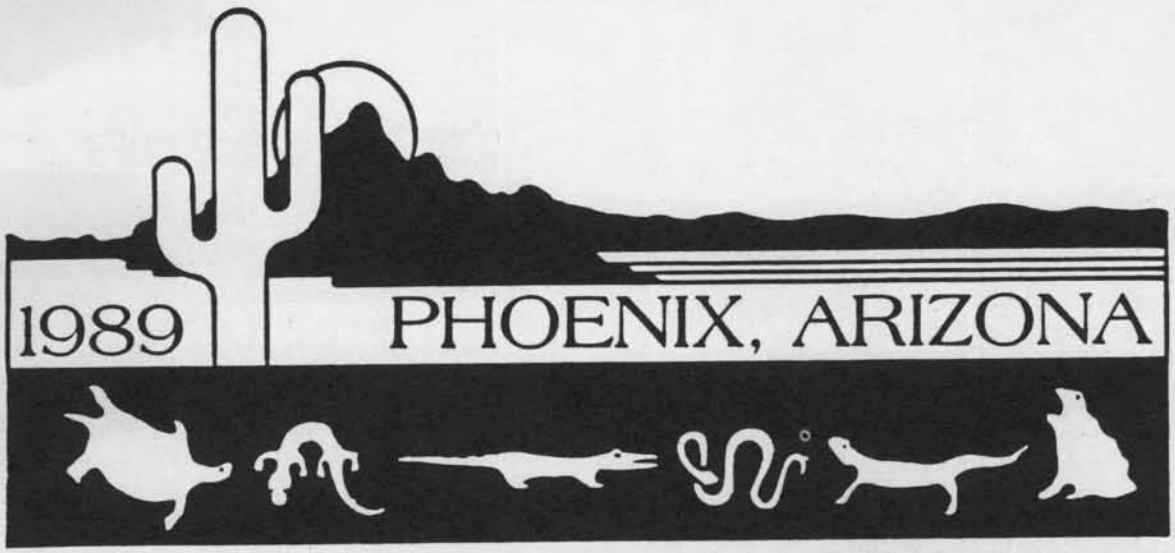
NEW SNAKE RECORDS FOR BOTSWANA, SOUTHERN AFRICA

Up-to-date information on snake distribution in Botswana is summarized in Broadley's "FitzSimons Snakes" (1983. Delta Books, Johannesburg). The authors have been collecting in southern Botswana from 1985 through March 1987. This paper details new records and range extensions in that area. Many of these species are listed from southeast Botswana (Auerbach 1985. The Reptiles of Gaborone. Botswana Book Centre. 48 pp.), but are speculative, without precise locality citations. To avoid repetition, coordinates of the two major localities are given here: Otse village (25°02'S, 25°45'E); Molepolole - Letlhakeng road = paved road running NW SE between Molepolole (24°26'S, 25°34'E) and Letlhakeng (24°03'S, 25°04'E). Specimens were deposited in the Natural History Museum of Zimbabwe (NMZB) and identifications were verified by D. G. Broadley, unless otherwise noted.

TYPHLOPS S. SCHLEGELII (Schlegel's Blind Snake). Moeding College, Otse. 17 March 1987. S. Spawls. (NMZB 8761). Southernmost record in Botswana, westernmost record in southern Africa, extends range 100 km SW.



TYPHLOPS LALANDEI (Delalande's Blind Snake). Moeding College, Otse. 24 February 1985. S. Spawls. (NMZB 7849). First record for Botswana S of 23° S, fitting in the gap between the Mafeking, South Africa (80 km S) and Shoshong (250 km N) records.

TYPHLOPS BIBRONII (Bibron's Blind Snake) 5km S of Otse. 19 March 1986. S. Spawls. (NMZB 8401). First record for Botswana, extends range 100km N.

LYCOPHIDION C. CAPANSE (Cape Wolf Snake). 8km SSW of Otse. 10 December 1985. S. Spawls. Verified by R. C. Drewes. California Academy of Sciences(CAS 160793). First record for Botswana S of 25°S. Fits in the gap between the Madibogo, South Africa (150km S) and Molepolole (80km N) records.

MEHELYA C. CAPENSIS (Cape File Snake). Moeding College, Otse. 14 January 1986. S. Spawls. (NMZB 8582). First record S of 25°S in Botswana, extends range 80km S; 13km NW of Molepolole, Molepolole-Letlhakeng road. 20 November 1986. J. de Graff. (NMZB 8621). Extends range 50km W. First record for Kalahari sand area.

PSAMMOPHIS LEIGHTONI TRINASALIS (Fork-marked Sand Snake). Jwaneng (24°30'S, 24°50'E). 9 May 1985. S. Spawls. (NMZB 7831). Fits in the gap between the Pretoria, South Africa, area (300km SE) and western Kweneng (200km W); Molepolole village. 28 August 1986. J. de Graff. NMZB 8747). Extends range 100km NE from previous record.

INTERNATIONAL HERPETOLOGICAL SYMPOSIUM, INC.

Dear Fellow Herpetologist:

On behalf of the advisors and directors, I would like to invite all members of SSAR to attend "Phoenix '89," the 13th Annual Meeting of the International Herpetological Symposium, Inc. The IHS has long been one of the premiere forums for amateur and professional herpetologists to meet and share information and ideas. With the excellent program of papers, workshops, and sidetrips detailed on the following pages, attendance this year is expected to exceed 350. As you will note from the program, topics cover a wide range from husbandry and captive propagation to physiology, ecology, and veterinary medicine.

We hope to see you there.

Brian P. Backner, M.D.
President, IHS, Inc.

INTERNATIONAL HERPETOLOGICAL SYMPOSIUM, INC.

PHOENIX, ARIZONA
JUNE 20-24, 1989
Program

TUESDAY, JUNE 20

9:00 am - 4:00 pm	Registration
Noon - 4:00 pm	Workshops
6:00 pm - 8:00 pm	Ice breaker (2 hour open bar)

WEDNESDAY, JUNE 21

8:00 am - 9:00 pm	Registration
9:00 am - 3:00 pm	Trip to Arizona-Sonoran Desert Museum
3:30 pm - 5:00 pm	Tour Reid Park Zoo
5:00 pm - 7:00 pm	Mexican Buffet Dinner, Reid Park Zoo

THURSDAY, JUNE 22

8:00 am - 9:00 pm	Registration
9:00 am - 3:50 pm	General Sessions
4:00 pm - 5:30 pm	Tour World Wildlife Zoo
6:30 pm - 9:00 pm	Rawhide -- Cookout

FRIDAY, JUNE 23

8:00 am - 9:00 pm	Registration
9:00 am - 3:50 pm	General Sessions
4:30 pm - 5:30 pm	Tour Boyce Thompson Arboretum
6:00 pm - 8:00 pm	Cowboy Cookout at the Arboretum

SATURDAY, JUNE 24

9:00 am - ?	General Sessions, Workshops

WORKSHOPS

1. Crimes of Fashion - Striking Back at the Skin Trade
   Dez Crawford, President, Louisiana Herpetological Society, Baton Rouge, LA
2. Husbandry and Breeding of Tortoises
   Brett Stearns, Institute for Herpetological Research, Stanford, CA
3. Husbandry and Breeding of Turtles
   Brett Stearns, Institute for Herpetological Research, Stanford, CA
4. Parasitology for the Serious Herpetoculturist
   Richard S. Funk, D.V.M., Knoxville, TN and Roger J. Klingenberg, D.V.M., Greeley, CO
5. Breeding Strategies for Colubrid Snakes
   Robert Applegate, Private Breeder, El Cajon, CA
6. Construction of Terrarium Environments Suitable for Amphibians
   Dale Bertram, M.D., Dendrobatid Society, Madison, WI
7. The Captive Breeding of Rare Pythons and Boas
   Donald Hamper, Private Breeder, Columbus Zoo
8. Antibiotic Usage in Reptiles
   Robert Wagner, D.V.M., Pittsburgh Zoo, Pittsburgh, PA and Megan Hilf, M.S., University of Pittsburgh, Pittsburgh, PA

PAPERS

Venomoid Surgery
-- Richard S. Funk, D.V.M., University of Tennessee, Knoxville, TN

A Safe, Practical Facility for Breeding Large Pythons
-- Ernie Wagner, Captive Bred Reptiles, Seattle, WA

Regurgitation Syndrome in Boids
-- Richard A. Ross, M.D., M.P.H., Institute for Herpetological Research, Stanford, CA

The First North American Breeding of the Mandarin Rat Snake, *Elaphe mandarina*
-- William B. Gillingham, Private Breeder, Stockton, CA

Reproductive Biology and Current Status of the Louisiana Pine Snake, *Pituophis melanoleucus ruthveni*
-- Steven B. Reichling, Assistant Curator, Memphis Zoo and Aquarium, Memphis, TN

Diagnostic Techniques in Reptile Medicine
-- Howard Martin, D.V.M., Assistant Professor of Zoological Medicine, Colorado State University, Fort Collins, CO

The Last Resort -- Techniques Used to Tube or Force Feed Chelonians
-- Ellen Nicol, Artist/Author/Reptile Breeder, Anthony, FL

Hibernation in Reptiles: A Review
-- Steven D. Garber, Department of Biology, Rutgers University, Piscataway, NJ

The Pathological Findings of Failed Reproduction in Kingsnakes: Ideas on Reproductive Medical Problems
-- Roger Klingenberg, D.V.M., Private Practitioner, Greeley, CO

The Care and Breeding of the Gargoyle Gecko, *Rhacodactylus auriculatus*, with Suggestions on Breeding *Rhacodactylus chahoua*
-- Jeffrey Nunan, San Diego, CA

Captive Behavior and Reproduction of the Burmese Mountain Tortoise
-- Richard Fife, Private Breeder, Phoenix, AZ

The Influence of Barometric Pressure on Reproduction in Reptiles
-- Richard Fife, Private Breeder, Phoenix, AZ

Captive Husbandry and Breeding of Dendrobatid Frogs
-- Erik Wevers, Wierden, Holland

Maintenance Strategies for Large Private Collections of Chelonians
-- Eric Olsen, Cleveland, OH

Captive Husbandry and Breeding of the Green Iguana
-- Roger Cogan, Phoenix, AZ

Breeding on Thin Ice -- Husbandry and Propagation of the Malagasy Tomato Frog
-- Phillipe de Vosjoli and Robert Mailloux, Private Breeders, Lakeside, CA

The Possible First Captive Breeding of *Rana ishikawae*, a Rare Ranid Frog from Okinawa
-- Phillipe de Vosjoli and Robert Mailloux, Private Breeders, Lakeside, CA

Captive Reproduction of the Banded Rock Rattlesnake, *Crotalus lepidus klauberi*
-- Gary Swinford, Chaparral, NM

Treatment of Dehydration and Starvation in Reptiles
-- Thomas H. Boyer, School of Veterinary Medicine, Colorado State University, Fort Collins, CO

On the Crawl! A Herpetological Look at Arizona
-- Cecil R. Schwalbe, Ph.D., Arizona State Herpetologist, Phoenix, AZ

Update on Pharmaceuticals Useful in Reptile Medicine
-- Scott J. Michaels, D.V.M., R.Ph.., Private Practitioner/Reptile Breeder, Urbana, IL

Thermoregulation in Reptiles -- Its Impact on Terrarius Design
-- Robert F. Mackin, Private Breeder, Bellevue, WA

Reproduction in Pythons at the Oklahoma City Zoo with Emphasis on *Liasis* and *Morelia*
-- Scott Wheeler, A.H.T.I., Oklahoma City Zoo, Oklahoma City, OK

Captive Propagation of the Black Eared Frog, *Leptodactylus melanonotus*
-- Craig Ivani, Arizona Sonoran Desert Museum, Tucson, AZ

It is IHS, Inc. policy to prohibit live animals at all Symposium functions. Presentors wishing to use live animals for diplay purposes must first contact Dr. Brian P. Backner.

The Society for the Study of Amphibians and Reptiles Announces Two New Books
To Be Published in Fall 1989 to Commemorate the First World Congress of Herpetology

SNAKES OF THE *AGKISTRODON* COMPLEX

by the late Howard K. Gloyd and Roger Conant

THIS LONG-AWAITED WORK is the first monographic treatment of the poisonous snakes originally included in the genus *Agkistrodon* but now placed in four genera: *Agkistrodon* of Asia and America, *Calloselasma* of Southeast Asia and Java, *Deinagkistrodon* of China, and *Hypnale* of India and Sri Lanka. In all, 33 taxa are covered. For each taxon there is a chresonymy, followed by sections entitled Type Locality, Vernacular Names, Definition and Diagnosis, Scutellation, Hemipenis, Coloration and Pattern, Form and Size, Distribution, Specimens Examined, Natural History and Ecology.

The book is extensively illustrated, with a color frontispiece (from a watercolor by David M. Dennis), 32 color plates (247 separate photographs of animals and their habitats), 20 black-and-white plates (of skin patterns, heads, and entire animals), 60 text figures, and 28 maps showing distribution. There are also 14 tables and 6 charts.

The authors of the main text have been two of America's most respected authorities on snakes for over half a century and during that time have published numerous papers on snakes of the *Agkistrodon* complex. This book represents the culmination of decades of detailed study of more than 6200 specimens, field work by the authors in many parts of the range of these snakes, and the synthesis of everything that is known about their systematics and natural history. Their text includes a comprehensive bibliography of nearly 2000 titles.

This book is also packed with discussions of general interest, including the following:

• The Cantil, *Agkistrodon bilineatus*, which survives through a severe annual season of drought by aestivating, and should not be called the Mexican "water" moccasin. On the opposite side of the world the Malayan Pit Viper, *Calloselasma rhodostoma*, endures a similar quiescent period, and occurs only in regions that have an annual dry season of a month or more.

• Vipers, esteemed as "medicine" in the Orient, are believed to cure a variety of ailments ranging from impotence to serious diseases. A favorite way to obtain the greatest benefit is to kill a snake, remove the gall bladder, and swallow it at once with a glass of rice wine.

• The Himalayan Pit Viper, *Agkistrodon himalayanus*, has been reported from 16,000 feet (4877 m), probably the highest elevation ever recorded for a snake.

• A full dozen taxa of pit vipers, including subspecies, was swept for decades into a taxonomic "wastebasket," labelled *Agkistrodon halys*. The Asian snakes of the genus *Agkistrodon* are much smaller, in both length and bulk, than the American copperhead, *Agkistrodon contortrix*.

• Special essays included are "The Mamushi Industry in Japan" by Richard C. Goris and "American Copperhead in History, Folklore, and Religion" by Roger Conant.

Supplementing this main text are nine ancillary chapters, each written by leading specialists on various topics of relevance, including behavior, chromosomes, fossil history, literature on venoms and envenomation, osteology and myology, hemipenes, immunologic relationships, and historical biogeography.

A complete list of the book's contents and a specimen color plate are given on the following pages. The book is about 550 pages (8.5 x 11 inches or 21.5 x 28 cm) and is bound in library-grade buckram cloth.

CONTRIBUTIONS TO THE HISTORY OF HERPETOLOGY

by Kraig Adler, John S. Applegarth, and Ronald Altig

(FULL DETAILS ARE GIVEN ON PAGE FOUR OF THIS ADVERTISEMENT.)

PRICES AND ORDERING INSTRUCTIONS. Books can be obtained from the Publications Secretary, Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103, USA. Please make check payable to "SSAR"; receipt sent on request. Prices include shipping charges (book rate) within USA; all overseas orders will be billed only for the *additional* costs in excess of domestic rates. Publications sent at customer's risk; however, packages can be insured at cost. Overseas customers must make payment in USA funds, by International Money Order, or by MasterCard or VISA (in which case account number and expiration date must be provided).

GLOYD & CONANT: SNAKES OF THE *AGKISTRODON* COMPLEX
( ) Prepublication price to SSAR members if ordered before 1 July 1989.....$60
( ) Price to Institutions, Non-members, and to all purchasers after 1 July 1989.....$75

ADLER ET AL.: HISTORY OF HERPETOLOGY
( ) Prepublication price to SSAR members if ordered before 1 July 1989.....$15
( ) Price to Institutions, Non-members, and to all purchasers after 1 July 1989.....$20

Both books will be published in Fall, 1989. The Society publishes *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Herpetological Circulars, Contributions to Herpetology* (monographs), and *Catalogue of American Amphibians and Reptiles*. Pricelist and information on Society membership are available on request from Dr. Aldridge.

SNAKES OF THE *AGKISTRODON* COMPLEX: A MONOGRAPHIC REVIEW

by the late Howard K. Gloyd and Roger Conant

TABLE OF CONTENTS

Preface
Introduction
- History and Scope of the Work
- Material Studied--Designations for Collections
- Terminology, Methods, and Definitions
- Locality Records, Geography, and Distribution Maps
- Tables and Charts; Illustrations
- Miscellanea; Acknowledgments

Taxonomic Status of the *Agkistrodon* Complex
The Four Genera
Checklist of Taxa Included in This Volume, With Derivations of Scientific Names
Description of the Genus *Agkistrodon* Palisot de Beauvois, 1799
- Use of *Agkistrodon* versus *Ancistrodon*

Introduction to the New World Species of *Agkistrodon*
The Cantil, *Agkistrodon bilineatus*
- *Agkistrodon bilineatus bilineatus* (Günther)
- *Agkistrodon bilineatus russeolus* Gloyd
- *Agkistrodon bilineatus howardgloydi* Conant
- *Agkistrodon bilineatus taylori* Burger and Robertson

The Copperhead, *Agkistrodon contortrix*
- Copperheads in History, Folklore, and Religion
- *Agkistrodon contortrix contortrix* (Linnaeus)
- *Agkistrodon contortrix mokasen* Palisot de Beauvois
- *Agkistrodon contortrix phaeogaster* Gloyd
- *Agkistrodon contortrix laticinctus* Gloyd and Conant
- *Agkistrodon contortrix pictigaster* Gloyd and Conant

The Cottonmouth, *Agkistrodon piscivorus*
- *Agkistrodon piscivorus piscivorus* (Lacépède)
- *Agkistrodon piscivorus conanti* Gloyd
- *Agkistrodon piscivorus leucostoma* (Troost)

Key for the Identification of the New World Taxa
Introduction to the Old World Species of *Agkistrodon* (*sensu stricto*)
Asian and North American *Agkistrodon* (*sensu stricto*): External Morphological Comparisons
The Monotypic Asian Species of *Agkistrodon*
- *Agkistrodon caliginosus* Gloyd
- *Agkistrodon himalayanus* (Günther)
- *Agkistrodon monticola* (Werner)
- *Agkistrodon strauchi* (Bedriaga)

The *Agkistrodon blomhoffii* Complex
- *Agkistrodon blomhoffii blomhoffii* (H. Boie)
- *Agkistrodon affinis* (Gray)--*Incerta Sedis*
- *Agkistrodon blomhoffii brevicaudus* Stejneger
- *Agkistrodon blomhoffii dubitatus* Gloyd
- *Agkistrodon blomhoffii siniticus* Gloyd
- *Agkistrodon blomhoffii ussuriensis* (Emelianov)

The *Agkistrodon halys-intermedius* Complex With Special Emphasis on *A. intermedius*
- *Agkistrodon halys halys* (Pallas)
- *Agkistrodon halys caraganus* (Eichwald)
- *Agkistrodon halys cognatus* (Gloyd)
- *Agkistrodon intermedius intermedius* (Strauch)
- *Agkistrodon intermedius caucasicus* (Nikol'skii)
- *Agkistrodon intermedius saxatilis* (Emelianov)
- *Agkistrodon intermedius stejnegeri* (Rendahl)

Relationships of Old World *Agkistrodon* to Those of the New World
Key for the Identification of the Old World Taxa of *Agkistrodon*
Key to the Four Genera, *Agkistrodon (sensu lato)*, *Calloselasma*, *Deinagkistrodon*, and *Hypnale*
Description of the Genus *Calloselasma* Cope, 1860
The Malayan Pit Viper, *Calloselasma rhodostoma*: Distinctions and General Comments
- *Calloselasma rhodostoma* (F. Boie)

Description of the Genus *Deinagkistrodon* Gloyd, 1979
The Hundred-Pace Viper, *Deinagkistrodon acutus*: General Comments
- *Deinagkistrodon acutus* (Günther)

Description of the Genus *Hypnale*
The Hump-Nosed Vipers of the Genus *Hypnale*
- Nomenclatorial History
- *Hypnale hypnale* (Merrem)
- *Hypnale nepa* (Laurenti)
- *Hypnale walli* Gloyd

Key to the Species of *Hypnale*
Phylogeny and Zoogeography of the *Agkistrodon (sensu lato)* Complex
General Summary (to be followed by translations in Chinese, Japanese, Russian, and Spanish)
Literature Cited

Postscript

Taxonomic Additions and Adjustments Proposed Since 1978
The Status of the Genus *Gloydius*
Chinese Geographical Names: Changes in Spelling

Ancillary Papers

Ritualized Behavior in *Agkistrodon* and Allied Genera, by Charles C. Carpenter and James C. Gillingham
Chromosomes of *Agkistrodon* and Other Viperid Snakes, by Charles J. Cole
The Fossil History of the Genus *Agkistrodon* in North America, by Roger Conant
The Palearctic Species of *Agkistrodon*, by Howard K. Gloyd
An Updating of the Literature on Venoms and Envenomation in *Agkistrodon* and Its Allies, by David L. Hardy
General Skull, Bone, and Muscle Variation in *Agkistrodon* and Related Genera, by Kenneth V. Kardong
A Review and Comparison of Hemipenial Structure in the Genus *Agkistrodon (sensu lato)*, by Edmond V. Malnate
Immunologic Relationships in *Agkistrodon* and Related Genera, by Sherman A. Minton
Pleistocene Forests and Copperheads in the Eastern United States, and the Historical Biogeography of New World *Agkistrodon*, by Thomas R. Van Devender and Roger Conant

CONTRIBUTIONS TO THE HISTORY OF HERPETOLOGY

by Kraig Adler, John S. Applegarth, and Ronald Altig

THIS BOOK consists of three separate sections, each of them worldwide in coverage and including herpetologists of both past and present. **The first and longest section, by Kraig Adler,** is a series of detailed biographies of the leading contributors to herpetology -- each complete with a portrait, signature, and references to other biographical information -- followed by an extensive bibliography of historical works in herpetology. These biographies feature 140 persons, but also included in them is information about their colleagues and students, so that the effective coverage is more than 500 individuals. A wide range of personages is included, from gifted amateurs sometimes having no formal education at all to the most distinguished and influential people of their day: princes, counts, an ambassador, priests, university presidents, several museum directors, and a peer of France. Biographies are arranged chronologically in order that the development of the field of herpetology can be visualized. There is a comprehensive index.

The 140 biographies include these 98 persons:

• Leading herpetologists such as Boulenger, Cope, Daudin, the Duméril, Fitzinger, Merrem, Mertens, Noble, Wilhelm Peters, Schlegel, Schmidt, Stejneger, Strauch, Wagler, and Werner.

• Great naturalists who dabbled in herpetology: Agassiz, Cuvier, Gessner, and Linnaeus.

• The explorers Espada, Maximilian, Spix, and Tschudi.

• Collection builders Baird, Barbour, Boettger, Gray, Günther, Logier, Seba, Steindachner, and Van Denburgh.

• The popularizers Ditmars, Kauffeld, and Vogel, the terrarist Klingelhöffer, and serious amateurs Klauber and Malcolm Smith.

• Authors of herpetological textbooks (Goin, Terentjev), prominent teachers (Boring, Myers, Ruthven, Wright), anatomists (Baur, Bojanus, Camp, Haas, A. S. Romer), and ecologists (Blair, Cowles, Tinkle).

• The artists Roesel von Rosenhof and Sordelli.

The coverage is comprehensive, including:

• Geographic areas such as the USA (Cochran, Garman, Girard, Harlan, Holbrook, James Peters, Pope, Rafinesque, Say, Taylor), Australia (Glauert, Kinghorn, Krefft, Mitchell, Waite), Africa (Anderson, Bocage, FitzSimons, Loveridge, Pitman, A. Smith, Villiers), and Russia (Bedriaga, Chernov, Nikolsky).

• Experts on taxonomic groups such as frogs (Liu, Miranda Ribeiro, Okada), salamanders (Bishop, Dunn, Sato), turtles (Carr, Deraniyagala, Schöpf, Siebenrock), and snakes (do Amaral, Blanchard, Gloyd, Jan, Maki, Oshima, Russell, and Wall).

The second section, by John S. Applegarth, is an index of over 2400 authors in taxonomic herpetology, an unique reference for researchers, librarians, and historians. Included is everyone who has ever proposed a new taxon within the living families of amphibians and reptiles, as well as persons who were honored by such taxa *and* who authored at least one contribution to herpetology. Authors are identified by their full names, exact dates of birth (and, if applicable, death), countries of residence, and the taxonomic orders in which they proposed new names.

The third section, by Ronald Altig, is a listing of herpetologists giving the names of their university and major professor, and the date of their doctoral degree. The information is arranged in such a manner that the academic lineages of herpetologists can be followed from generation to generation. About 1300 names are included and fully indexed.

The book is about 200 pages long (8.5 x 11 inches or 21.5 x 28 cm) and is bound in library-grade buckram cloth. There is a color frontispiece and 140 photographs. The sample biography printed below is reduced in format from actual size in the book.

COPE, E. D. (1840-1897).

Edward Drinker Cope, vertebrate paleontologist, anatomist, and America's greatest herpetologist, was born in Philadelphia on 28 July 1840. In school he was drilled in the classics and later in languages by a private tutor, but it was Cope's father, a wealthy merchant, who fostered his interest in natural history but for an intended career in agriculture instead. During the summers of 1854-1860 young Cope was sent to work on the farms of various relatives and he spent his spare time in the fields and meadows collecting salamanders and snakes. Previously, in 1846, at the age of six, he had made a visit to the museum of the Academy of Natural Sciences in Philadelphia which, judging from his extensive notes about the trip, had a profound affect on him. By 1859 he was already a volunteer worker at the Academy, busily engaged in reorganizing the herpetological collection, and at the age of 18 he published his first paper, describing two new salamanders and proposing modifications in the classification of the group. Although Cope's interests later broadened to include all vertebrate groups, herpetology was his first love and favorite branch of study and it continued to occupy him for the rest of his life.

Cope pleaded with his father to let him attend the University of Pennsylvania to study comparative anatomy with Joseph Leidy, under the ruse that it would permit him to treat farm stock, and he finally was allowed to do so in 1860-1861. It was the only formal course in science that Cope ever had! It soon became clear that he would never be happy as a farmer. His father relented and permitted him to pursue his informal studies by spending the winters of the Civil War years of 1861-1863 in Washington, where he became the protégé of Spencer F. Baird. In 1863-1864 Cope travelled throughout Europe, where he had the opportunity to meet and work with some of the leading anatomists and herpetologists of the day, including John E. Gray and Albert

Edward D. Cope

but beginning 1872 their famous feud began, which eventually involved dirty tricks, spying, charges of plagiarism and, in 1890, sensational headlines in a series of articles in the New York *Herald* newspaper. The competition became so fierce that Cope got into the habit of hurriedly studying his newly- collected material in the field and then promptly telegraphing his descriptions to Eastern journals, but several times the telegraph operators got the names of his new species garbled--and for all posterity! The dispute ended only with Cope's death, but by that time the rivalry had engulfed America's leading scientific institutions and academies and many biologists and paleontologists, including the herpetologist Georg Baur, Marsh's chief assistant who was secretly Cope's ally.

Cope's father died in 1875 leaving him an inheritance in excess of a quarter million dollars. With such enormous

The checklists of North American (1875) and Central American and Mexican (1887) amphibians and reptiles were important catalogues for reference. His "Classification of the Ophidia" (1895, preliminary paper in 1894) introduced still another important and useful anatomical characteristic, snake hemipenes; those of lizards he published in 1896. Cope's most widely known books on herpetology, however, were published toward the end of his career but were begun many years before. "The Batrachia of North America" (1889, reprinted 1963) was based on a manuscript and drawings by Baird and Charles Girard, to which Cope added his own material, chiefly anatomical. Cope's last work, "The Crocodilians, Lizards, and Snakes of North America" (1900), was published posthumously. It, too, was partly based on a Baird manuscript (lizard section only), but the book was never fully completed due to Cope's premature death (the turtles, however, were omitted on account of Baur's intended, but never published monograph on the subject). Both books are still standard texts on North American herpetology, containing much information on external structure and anatomy and illustrated by numerous plates.

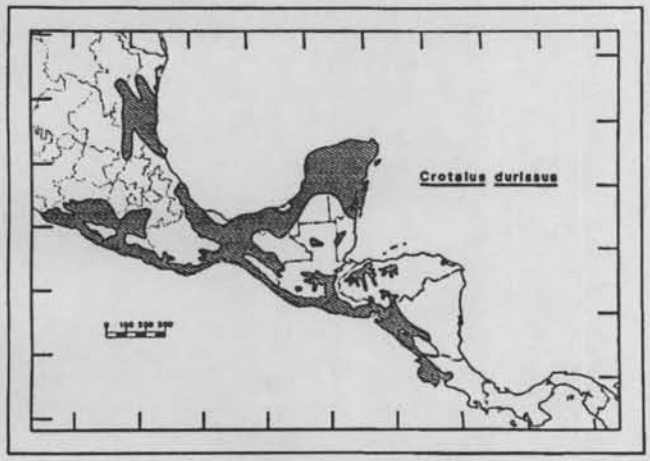
SEE YOU IN ORLANDO IN '90!



SPECIAL OFFER TO MEMBERS OF THE HERPETOLOGISTS' LEAGUE

THE VENOMOUS REPTILES OF LATIN AMERICA

BY JONATHAN A. CAMPBELL AND WILLIAM W. LAMAR

This magnificent volume provides the first comprehensive treatment of all dangerously venomous reptiles in Latin America. Included are detailed descriptions of 145 species of snakes and 2 species of lizards with discussions of their coloration, scutellation, distribution and habitat. Regional accounts for all countries--Mexico to Argentina--contain tables of distribution and identification keys. The book also has a section on medical aspects of snakebite and a bibliography and guide to producers of antivenom.

A MUST FOR ALL HERPETOLOGISTS

COVERS 147 SPECIES INCLUDING NEARLY ALL THOSE IN THE U.S.

- 504 color photographs
- 62 line drawings
- 115 maps, 6 color maps
- 440 pages

LC 88-47934; ISBN 0-8014-2059-8
Cornell University Press, June, 1989

Publisher's List Price $59.50

Pre-publication Price (until May 31, 1989)* **$39.50**
After June 1, 1989* **$45.00**
*postage included

Send check made payable to THE HERPETOLOGISTS' LEAGUE to: Ellen J. Censky, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Avenue, Pittsburgh, PA 15213, U.S.A.

APARALLACTUS CAPENSIS (Cape Centipede-eater). Maladiepe Hill, 1km NE of Otse village. 21 June 1985. S. Spawls. (NMZB 7844). First record S of 25°S in Botswana. Extends range 50km S.

AMBLYODIPSAS VENTRIMACULATA (Kalahari Purple-glossed Snake). 20km NW Molepolole, on Molepolole-Letlhakeng road. 30 October 1986. J. de Graff. (NMZB 8603). First record S of 23°S and E of 24°E in Botswana. Extends range 450km SE.

AMBLYODIPSAS P. POLYLEPIS (Common Purple-glossed Snake). 10km NW Molepolole, on Molepolole-Letlhakeng road. 5 November 1986. J. de Graff. (NMZB 8610). First record S of 21°S in Botswana; the only record between Okavango (500km NNW) and Pretoria, South Africa, (400km E).

XENOCALAMUS MECHOWII INORNATUS (Elongate Quill-snouted Snake). 22km NW Molepolole, on Molepolole-Letlhakeng road. 3 November 1986. J. de Graff. (NMZB 8612). First record S of 21°S in Africa; extends range 560km S.

XENOCALAMUS B. BICOLOR (Variable Quill-snouted Snake). 33km NW Molepolole, on Molepolole-Letlhakeng road. 25 October 1986. S. Spawls and J. de Graff. (NMZB 8672). Fits in the gap between Gaborone record (65km E) and the Kutse Pan record (130km NW).

ATRACTASPIS BIBRONII (Bibron's Stiletto Snake). 2km N of Otse. 17 October 1986. S. Spawls. (NMZB 8683). Fits in the gap between the Vryburg, South Africa, (250km S) and the Sikwane (80km NE) records 40km NW Molepolole, on Molepolole-Letlhakeng road. 25 October 1986. S. Spawls and J. de Graff. (NMZB 8593). Extends range 90km NNW of previous record.

PROSYMNA SUNDEVALLI LINEATA (Lineolate Shovel-snout). 20km N of Molepolole. J. de Graff.(NMZB 8306). First record for Botswana S of 21°S, extends range 500km SE; 55km NW Molepolole, on Molepolole-Letlhakeng road. 25 October 1986. S. Spawls and J. de Graff. (NMZB 8674). Extends range 40km W of previous record.

CROTAPHOPELTIS HOTAMBOEIA (Red-lipped Snake). 8km SSW of Otse. 24 March 1986. S. Spawls. Verified by R. C. Drewes. California Academy of Sciences(CAS 160777). First record from Botswana S of 20°S. Extends range 60km NW (from South Africa); 15km NW Molepolole, on Molepolole-Letlhakeng road. 29 October 1986. J. de Graff. (NMZB 8600). First record from Kalahari sand area in Botswana. Extends range 90km NNW.

DISPHOLIDUS TYPUS (Boomslang). Moeding College, Otse. 19 February 1985. S. Spawls. (NMZB 7798). First record for SE Botswana, although recorded ca. 20km E in South Africa.

THELOTORNIS C. CAPENSIS (Southern Vine Snake). 12km SSW of Otse. 20 April 1985. S. Spawls. (NMZB 7711). First record for SE Botswana S of the Tropic of Capricorn. Extends range in Botswana 300km SE.

DENDRASPIS POLYLEPIS (Black Mamba). Otse village. 23 March 1987. S. Spawls. (NMZB 8762). Southernmost record in Botswana. Extends range 50km S.

ACKNOWLEDGMENTS

Our thanks to D. G. Broadley, Natural History Museum of Zimbabwe, Bulawayo, for identifying the specimens and critically reading the manuscript, and to our wives Laura and Frieda for tolerating their snake-hunting husbands.

NEW STATE RECORDS FROM NORTHERN GUERRERO, MEXICO

While doing a survey of the herpetofauna of the Sierra de Taxco, Northern Guerrero, Mexico, we collected 42 species of herps belonging to that area from which 20 are new records for the Sierra de Taxco, and 9 are new state records (discussed below). Most of the new recorded species belong to the fauna of the Mexican Volcanic Axis; because of this, we consider the Sierra de Taxco as a part of that mountain system (Hernandez and Flores, unpublished data).

All specimens were collected by the second author (EHG), verified by Guillermo Lara Gongora, and are deposited in Museo de Zoologia Facultad de Ciencias (MZFC) at the National University of Mexico.

The species recorded for the first time from Sierra de Taxco are: *Pseudoeurycea b. belli,* Municipios de Tetipac, and Taxco (MZFC 3798, 3799); *Bufo occidentalis,* Municipios de Tetipac, Ixcateopan de Cuahutemoc, Taxco, and Almololoya de Alquiciras (MZFC 3749-51, 3755, 3759, 3752-53, 3760, 3754, 3756-57, 3761, 3758); *Hyla eximia,* Municipio de Tetipac, (MZFC 3786-90); *Tomodactylus dilatus,* Municipio de Ixcateopan de Cuahutemoc (MZFC 3765-67); *Anolis nebulosus,* Municipios de Tetipac, Ixcateopan de Cuahutemoc (MZFC 3831-33, 3838-40, 3843, 3834-37, 3841-42, 3844-56); *Sceloporus g. grammicus,* Municipios de Tetipac, Ixcateopan de Cuahutemoc, and Pedro Ascencio de Alquiciras (MZFC 3857, 3865-66, 3868, 3870-74, 3858, 3863-64, 3877-79, 3859-62, 3867, 3875, 3876); *S. mucronatus omiltemanus,* Municipios de Ixcateopan de Cuahutemoc, Pedro Ascencio de Alquiciras, and Tetipac (MZFC 3930, 3933-39, 3947-48, 3957-63, 3975-77, 3979, 3981, 3931, 3951, 3964, 3967, 3969-71, 3973-74, 3980, 3965-66, 3968, 3978, 3972); *Urosaurus b. bicarinatus,* Municipios de Tetipac (MZFC 3982-83); *Abronia deppei* Municipios de Tetipac, Ixcateopan de Cuahutemoc, and Pedro Ascencio de Alquiciras (MZFC 3993, 3992, 3991); *Gerrhonotus l. leiocephalus,* Municipios de Tetipac (MZFC 3602); *Cnemidophorus c. costatus,* Municipios de Tetipac, Ixcateopan de Cuahutemoc (MZFC 3913, 3915-16, 3919, 3914); *Drymarchon corais rubidus,* Municipio de Ixcateopan de Cuahutemoc (MZFC 3825); *Leptodeira splendida, bressoni,* Municipio de Ixcateopan de Cuahutemoc (MZFC 3819); *Masticophis mentovarius striolatus,* Municipios de Taxco, Tetipac, and Ixcateopan de Cuahutemoc (MZFC 3816, 3817, 3818); *Pituophis lineaticolis,* Municipios de Taxco and Tetipac (MZFC 3823, 3824); *Rhadinea hesperia,* Municipio de Ixcateopan de Cuahutemoc (MZFC 3815); *R. taeniata aemula,* Municipios de Taxco, Tetipac, and Pedro Ascencio de Alquiciras (MZFC 3811-12, 3814, 3813); *Salvadora bairdi,* Municipios de Taxco and Tetipac (MZFC3821, 3820); *Storeria storeroides,* Municipios de Taxco, Ixcateopan de Cuahutemoc, Pedro Ascencio de Alquiciras and Tetipac (MZFC 3801, 3800, 3803, 3805-10, 3804); and *Thamnophis cyrtopsis collaris* Municipio de Ixcateopan de Cuahutemoc (MZFC 3994).

The new State records are:

Rhyacosiredon rivularis; Municipio de Tetipac, 10 km by road from Taxco to Tetipac, Los Llanos; in cloud forest. June (day not recorded) 1986; 20 June, 21 July, 24 October 1986; 7 May 1987 (MZFC 3579-80; 3581-83; 3586-87; 3584-85; 3588-91). New record of the family Ambystomatidae for the State of Guerrero.

PSEUDOEURYCEA C. CEPHALICA; Municipio de Taxco, cerro Huizteco; in cloud forest. 7 June 1987. Municipio de Pedro Ascencio de Alquiciras, Cruz Alta; in cloud forest, 14 June 1987 (MZFC 3594-95, 3592-93).

ELEUTHERODACTYLUS HOBARTSMITHI; Municipio de Taxco, cerro Huizteco; in cloud forest. 8 and 9 June 1986, 27 April 1987. Municipio de Taxco, La Cascada; in cloud forest. 10 December 1986. Municipio de Ixcateopan de Cuahutemoc, las Peñas; in *Juniperus* forest. 8 November 1986. Municipio de Ixcateopan de Cuahutemoc, 1km W of Ixcateopan ; in *Juniperus* forest. 11 November 1986 (MZFC 3668, 3669, 3670, 3671, 3672, 3673 series of 11 specimens).

ELEUTHERODACTYLUS MEXICANUS; Municipio de Ixcateopan de Cuahutemoc, 1km W of Ixcateopan ; in *Juniperus* forest. 11 November 1986 Municipio de Tetipac, 10 km by road from Taxco to Tetipac; in cloud forest. 22 June 1986 (MZFC 3597, 3599, 3598). These specimens from Sierra de Taxco extend the range about 300km straight line from the nearest known locality at Cerro San Felipe, Oaxaca (Lynch 1965. Chicago Acad. Sci. Nat. Hist. Misc. (182): 12pp).

SCELOPORUS PALACIOSI; Municipio de Pedro Ascencio de Alquiciras, 500m SW Cruz Alta; in cloud forest. 11 September

1986. Municipio de Pedro Ascencio de Alquiciras, 1.5km SSW from Los Jarillos; in cloud forest. 12 September 1986 (MZFC 3600, 3601). This recently described species was previously recorded from Michoacan, Mexico, Morelos and Distrito Federal (Lara-Gongora 1983. Bull. Maryland Herp. Soc. 19:9).

CONOPSIS BISERIALIS; Municipio de Ixcateopan de Cuahutemoc, 26.5km by road from Taxco to Ixcateopan; in *Juniperus* forest. 26 July and 13 November 1986. Municipio de Taxco, cerro Huizteco; in cloud forest. 8 and 24 June 1986. Municipio de Tetipac, 10 km by road from Taxco to Tetipac, Los Llanos; in cloud forest. 20 June, 21 August, and 25 October 1986. Municipio de Pedro Ascencio de Alquiciras, Tres Cruces de Mamatla; in cloud forest. 7 December 1986 (MZFC 3606-7, 3614, 3611-12, 3604, 3608-10, 3603, 3605, 3613).

TANTILLA DEPPEI; Municipio de Ixcateopan de Cuahutemoc, El Salitre River; n *Juniperus* forest. 14 July 1986 (MZFC 3615). Very few precise localities, all of them in Morelos, are given for this taxon since the reassignment of the type locality by Davis and Smith (1953. Herpetologica 8:138).

CROTALUS T. TRISERIATUS; Municipio de Taxco, cerro Huizteco; in cloud forest. 22 and 23 August 1986. Municipio de Tetipac, 10 km by road from Taxco to Tetipac, Los Llanos; in cloud forest. 20 June 1986. Municipio de Tetipac, Arroyo las Damas; in cloud forest. No specific date (MZFC 3664, 3665, 3666, 3667).

ACKNOWLEDGMENTS

We wish to thank Antonio Muñoz, our students Fernando Cisneros and Laura Romero for their assistance in the field, and Roy McDiarmid for his kind help.

NEW DEPARTMENTAL RECORDS FOR NORTHEASTERN HONDURAN HERPETOFAUNA

During field work in Honduras in 1985, a number of specimens representing first records for the Departmentos de Gracios A Dios and Colon were collected. All reptiles and photographs were verified by A. F. Stimson; *Eleutherodactylus* by J. M. Savage; *Bolitoglossa* by B. Clarke. All preserved material was deposited in the British Museum (Natural History) (BMNH).

Depto. de Gracios A Dios

SPHAERODACTYLUS MILLEPUNCTATUS. Palacios, Laguna Bacalar. 20 April (BMNH 1985.1280).(Meyer & Wilson 1973. Los Angeles.Co. Mus. Contrib. Sci. (244):1-39, *S. continentalis* syn. *S. millepunctatus*, fide Harris and Kluge 1984. Occ. Pap. Mus. Zool. Univ. Mich. 706:1-59).

BOTHROPS SCHLEGELII. Rio Guaraska. 9 May (BMNH 1986.55). First record for northeastern Honduras. Extends range 250km E Lancetilla, western Atlantida and Mataderos Mts., central Yoro (Wilson & Meyer 1982 & 1985. op. cit.).

ACKNOWLEDGMENTS

The project field work for this project would not have been possible without the unstinting assistance of the Venturers and Staff on the Honduran phase of Operation Raleigh and to those people I am extremely grateful. Señor Wilberto Aquilar of RENARE gave permission for the project to take place in Honduras. I would also like to express thanks to Drs. Jay M. Savage, Larry David Wilson, and William E. Duellman for looking at some of my specimens and either confirming identification or reidentifying them. Thanks are also due to Mr. Andrew Stimson, Dr. Colin McCarthy and Mr. Barry Clarke at the British Museum (Natural History) for their advice and assistance and Dr. Larry David Wilson for reading and commenting on the manuscript.

BOOK REVIEWS

Sistemática de *Podarcis* (Sauria, Lacertidae) Ibéricas y Norteafricanas Mediante Tecnicas Multidimensionales, by Valentin Perez Mellado and M^{a}.P. Galindo Villardon. 1986. x + 163 + 51 (appendix) pp. Bibliography (130 refs.). Ediciónes Universidad de Salamanca, Ser. Manuales Universitarios. Faculdad de Biologia. Must be ordered from the publisher: Ediciónes Universidad de Salamanca, Patio Escuelas 1, Apartado 325, SP-Salamanca (Spain).

People working in systematics know how difficult it can sometimes be to integrate, at once, all individual and environmental data. In this way, multidimensional analyses, of recent use,

seem able to be very helpful for taxonomy and biogeography.

In the present book, a biologist, Perez Mellado, and a mathematician, Galindo Villardon, have tried to apply multivariate analyses to the much debated question of Iberian *Podarcis* systematics. No fewer than 79 "variables," including patterns and colors as well as meristic and metric characters, have been fed to the computers, starting with 16 *P. hispanica*, 4 *P. bocagei* and 9 *P. muralis* so-called "populations," i.e. regional samples comprising 387 local samples in all. A key to recognized forms is given pp. 146-147.

Beyond analyses, computers have been used for typing the book and drawing figures. This has made for rapid publication—too rapid, actually. A little more time devoted to presentation could have rendered pleasant and easy a reading which turns out to be exceedingly hard. Exhausting mental (and finger) gymnastics is imposed on the attentive reader. For instance, suppose you want to study population 12 in results tabulated pp. 73-75. The introductory chapter "Metodología", which defines every "variable" and "population," has told you that population 12 is the Tunisia sample group of *P. hispanica*. Well, you are in for a painful mistake: unobtrusively, somewhere in the Results (p. 65), pop. 12 has become the Grand Atlas sample group. Now you are interested in variable 52 of *P. bocagei* males as tabulated pp. 27-30? Don't you believe what the introduction tells you about var. 52! You have to browse first, at the end of the book, through a long Appendix (not referred to). After some search there, you find on its p. 22 that 52 stands for variable 34 not 52. By that time, maybe you have lost the page you started from. In other tables, however, numbers are those of the original data. The reader's headache is compounded by further discrepancies between tables ***within*** the appendix.

To the authors' credit, every single raw datum is published. But if they had made the effort of printing a fair copy rather than a rough draft of their book, Perez Mellado and Galindo Villardon would have at once avoided the extraordinary complications just described and the innumerable errors and omissions that come in addition, some of them impossible to correct with the information at hand. Casualness reaches a climax with illustrations. Moreover, a unique model has been used, as a frame for sketching color patterns, for both sexes, in spite of pronounced sexual dimorphism.

However, readers can perfectly well concentrate on pages 102-153. Best in the book, they could be titled "General Considerations" and, as a discussion basis for European lacertid specialists, are undoubtedly interesting, whether you share the authors' viewpoints or not. Once these pages have been read, in fact, the impression is that this book is either the work of a good herpetologist to whom mathematics unnecessarily serves as a vindication, or that of a mathematician on whose results a biologist lays extrinsic conclusions. Never does the synthesis appear, and one may wonder whether all the calculations are of any help to taxonomy. A risk is that people who only read the conclusions, or glance through all the book without studying it thoroughly, may think that the proposed taxonomic changes proceed from mathematical analysis. We think the latter is largely irrelevant, for the following reasons.

1) The trap of subjectivity could not be escaped. At least, we feel that selecting qualitative variables and making up "populations" was influenced by preconceived taxonomy. Furthermore, distinguishing variables 1-3 from variables 4-7, i.e. brown from green, is simply impossible with certain museum specimens of *Podarcis*.

2) Perez Mellado had distinguished *P. b. bocagei* and *P. b. carbonelli* in previous publications. Nothing significant is added to their respective traits.

3) The authors synonymise *P. muralis sebastiani*, an insular form, with *P. h. hispanica*. However, insular forms have not been included in the study (whose title should have "continental" within it, incidentally). The taxonomic decision is made on extraneous, "classical" grounds. (A note in press in Revista Española de Herpetologia, 1, 1, by Bea, Gosà, Guillaume and Geniez, reëstablishes *sebastiani* as a subspecies of *P. hispanica*).

4) An important point is whether the form *vaucheri* from North Africa exists or not in southern Spain. Perez Mellado and Galindo Villardon conclude not (pp. 147, 150), but their conclusion is independent from the multivariate analysis since "population" 11(10) from *P. hispanica* (Andalusia and south central Spain), being very sparse, could not permit any definitive judgement on this matter (p.78).

5) Quite revealing of subjectiveness are statements that contradict results on which they are commenting. One example: p. 70, a matrix shows variables 58, 63, 57, 19, 2, 15, 20, 42, and 35, in this order, to have the highest values. Yet in the facing text we are told that "the variables of major importance" are 58, 57, 19, 2, 15, 20, 64 and 31. Actually, the latter two rank 14th and 12th, respectively, in the matrix. (The reason to disregard variables in between is not stated).

6) Eliminating as variables "means which probably are strongly influenced by ecological conditions" is sheer arbitrariness.

Is this a condemnation of the method as applied to the subject dealt with? We know that multivariate analyses can disclose unanticipated relationships. While it can be hard to get rid of preconceived ideas in selecting characters, it is a pity for **Sistemática de *Podarcis* Ibéricas y Norteafricanas** that the analysis was started from predetermined sample combinations when the power of the method does allow to start from individual data. You can hardly expect, then, to get sounder results than Boulenger and other lacertid experts obtained with unaided brains.

Studies In Herpetology. Proceedings of the European Herpetological Meeting (3rd Ordinary General Meeting of the Societas Europaea Herpetologica) Prague 1985. Z. Rocek (ed.) Published by Charles University, Prague, for the Societas Europaea Herpetologica. 754 pp. Hardbound.

Almost 5 cm thick, nicely bound in signatures and entirely in English, this impressive volume summarizes the 1985 European herpetological meetings at Prague. An immense amount of effort went into the preparation of this tome. Loosely arranged into a dozen sections, the book includes 150 (!!!) concise scientific papers (4-5 pages each) covering a vast range of topics in herpetology including genetics, morphology, paleontology, physiology, behavior, biogeography, phylogeny and systematics, ecology, evolution, and conservation. Authors hail from literally dozens of countries, including Austria, Australia, Belgium, Brazil, Canada, Cuba, Czechoslovakia, Denmark, England, France, Germany, Greece, Hungary, Israel, Italy, the Netherlands, Nigeria, Norway, Poland, Romania, Russia, Spain, Sweden, Switzerland, the United States, and Yugoslavia.

A short review cannot do justice to all this research: my own favorite papers are several on Russian lizards, but there is a wealth of information here with something that will interest almost any herpetologist. Aside from offering a rare glimpse of contemporary European herpetology in English, perhaps the most important lesson to be gained from this volume is rather tragic. Habitat destruction in overpopulated Europe has reduced the herpetofauna to a mere vestige of what it must once have been — herpetologists in less-ruined countries must take heed immediately and begin working in earnest to halt human population growth and to preserve natural habitat in their own areas NOW.

Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986-1988? Privately Printed (Ralph W. Axtell, 2814 Rock Hill Road, East Alton, Illinois 62024). Pages variable, 4-16 in the five parts so far published. Map with each part. Price $1.00 for each part of 10 pages or fewer, $2.00 for parts of over 10 pp., plus postage of $0.60 for one part, $0.80 for two, $1.10 for three or more.

A monumental undertaking is under way in this modestly entitled work. Fortunately it lends itself to serialized publication, thereby assuring potential users that its availability does not hinge first upon completion in its entirety. It sets a new high standard for thoroughness that will be difficult to equal in any regional study. It is of standard 8.5x11 in. format, the text reproduced from word processor output. The 1988 accounts are punched for 3-ring notebooks.

Each species account is issued separately, except that one map serves for two accounts in two cases among the five thus far issued, the first in April, 1986, the most recent two in March, 1988.

The heart of each account is the list of localities, arranged in tabular form alphabetically by county and, under each county, the place names, followed in numerical order by the distances of the collecting sites from those place names. Museum source is cited for each locality, or in the absence of museum material, the literature source. Each locality is plotted on a large scale detailed map of the state, and a small scale insert map shows the total range of the species as a whole. The spots on the maps are small (about 0.75 mm in diameter, equivalent to 2.9-3.7 mi.), and do not overlap; acceptable localities are enclosed by projected range limits. An attractive innovation is the use of two colors for the spots on maps depicting localities for two species.

The number of records is exhaustively overwhelming. Fifty-one museums were canvassed, at least for the most recent accounts, yielding staggering totals of specimens (± 1120 for *Coleonyx brevis*, 450 for *Sceloporus cyanogenys* (which Olson 1988, Bull. Md. Herp. Soc., 23:158-167, regards as a subspecies of *S. serrifer*), 1380 for *S. poinsettii*, 645 for *S. variabilis*, 76 for *S. graciosus*, just from Texas!). The lists of "locality vouchers" are equally impressive (respectively, 459, 110, 444, 185, 19), with much of the space of each account devoted to them (e.g. 10 of 13 pp. for *C. brevis*).

On the bases of the distributional data thus collected, examination of much material, and extensive field experience, the author has ingeniously interpreted the significance of the distribution of each species as now understood in Texas. Paragraphs are devoted standardly to fourteen topics: Taxonomic Status, Synthesis of Texas Distribution (a detailed, regional analysis of habitats), Differentiation in Texas Populations, Population Density (past and present), Elevational Range in Texas, Earliest Vouchers Taken, Fossil Records in Texas, Erroneous or Questionable Records, Extinction Prone Populations, Potential New County Records, Herptiles With Similar Distributions in Texas (of the five species for which the accounts are completed, only *S. graciosus* has no distributional parallels in Texas), Future Work, Map Symbols, and Locality Vouchers.

The work thus is not of taxonomic intent; basic nomenclatural data are cited (original description, holotype, type locality, first use of combination, major reviews), but there is no review of the literature, inasmuch as Dixon thoroughly covered that aspect in 1987, and no review of natural history or biology. Under special circumstances (e.g., *S. variabilis*), a brief paragraph of "Taxonomic Comments" is added (in this case to correct the interpretation of holotype for *S. v. marmoratus*). In consistency with precedent, the barbarous spelling *arenicolous* was perpetuated for the Texas subspecies of *S. graciosus*. That subspecific name was obviously derived from Latin (for "sand-dweller"), and the erroneously anglicized -ous ending implied that it was applied as an adjective ("sand-dwelling"), but the latinized ending (required by Art. 11(b) of the Code) for an adjective in the nominative singular (Art 11(b)) is -us. Arts. 25, 26,32(c)(i)(d)(ii) make it clear that the original spelling *arenicolous* is incorrect and should be corrected to *arenicolus* .

In any event, Axtell's study demonstrates the irreplaceable value of an initially intensive geographic sampling, and also of the necessity of visual rather than repeated voucher confirmations in the future, if deleterious human-based pressures on native biota are to be minimized. The painstaking documentation and inspired interpretation this atlas represents deserve the attention, appreciation and, where appropriate, the emulation of every biologist — not only herpetologists.

The Evolution of Vertebrate Design, by Leonard B. Radinsky. University of Chicago Press, xi + 188 pp., 18 figs.; clothbound, $35.00; paperbound, $12.95.

It seems ever more important, in this dawning of the age of biotechnology, that students be educated to appreciate whole animals and their evolution. If your institution does not offer such a course to non-biology majors, this book provides both the vehicle and the incentive. Len Radinsky gave a course in vertebrate morphology, paleontology, and evolution for non-biologists at the University of Chicago, and his book is an outgrowth of that course. Len was a gifted teacher who loved teaching, and, if you know him, you find his grin, his intensity, and his concern for giving students a wealth of material in an engaging way emerging from the pages of the book.

The book is most admirable in its consistency of presentation. It is clearly written, with careful but succinct explanations. It presents a large body of information about animals, their histories, their structure, and their function. It introduces methods of research approaches and analyses, all in ways that non-scientists can understand and appreciate. The first chapter is the clearest non-specialist introduction to basic principles of phylogenetic analysis that I have read; specialists might examine it to see how they can incorporate such coherence. The second chapter is a fine discussion of pattern and process of evolution that assures without proselytizing. The third chapter presents the vertebrate body plan, the structural basis of vertebrate design. The remaining fifteen chapters discuss vertebrates in a general phylogenetic order. Most of the discussions are quite general, as is appropriate for a non-majors volume. However, each treatment presents information on the body plans of extinct taxa, and of extant forms, so that innovations, whether they persisted of not, are discussed in a framework of evolution of structure and function. Because of the book's relatively small size and emphasis on a careful but exciting presentation for non-scientists, some information that a vertebrate biologist might normally expect to be presented is omitted, and favorite major taxa are treated rather summarily. That is irrelevant to the purpose and focus of this book.

The illustrations are outstanding, virtually unique. The body plans of representative vertebrates are executed in a wonderfully consistent style, all as line drawings. External body shapes are clearly delineated and compared. Skeletons are presented in two forms: one being black structures within the body outline, the other beautifully rendered, stylized, quasi-biomechanical forms. The latter are particularly effective, for they permit a new and special kind of comparison of structure and function. Neither rendition of skeletons shows all the relevant bones, and many are never represented by the shapes they really have. This must not be criticized as lack of useful detail — they are perfect to make the points that the text treats. I consider them highly adaptable to use in more advanced courses as well. Feeding and locomotion are emphasized, and comparisons can be made among all the major groups of vertebrates, both extinct and extant. Many of the chapters also include simple, straightforward, up-to-date cladograms to illustrate

relationships and radiations within groups. The cladograms include small illustrations of skeletal morphology of representative taxa, further reinforcing the consistency of the theme of vertebrate design.

The book has much to offer vertebrate biologists as well. It would be excellent review for the general biology instructor; teachers of vertebrate morphology and paleontology will find many new ways of presenting concepts. Radinsky's framework allows more specific information about data and theory to be included, so it would work well in a diversity of more specialized courses. As already indicated, the illustrations are particularly innovative and useful, and in many contexts. The book is well priced and eminently suited to a diverse audience.

Len Radinsky has left the legacy of his teaching and research to students and colleagues through this delightful and conscientious little book, and we all owe Sharon Emerson our gratitude for seeing it to completion after Len's most untimely death. **The Evolution of Vertebrate Design** will serve students very well by introducing them to vertebrate animals through exploration of their structure, function, and history.

The Venomous Reptiles of Arizona, by Charles H. Lowe, Cecil R. Schwalbe and Terry B. Johnson. 1986. Arizona Game and Fish Department, Phoenix. i-ix, 115 pp, 24 Figures, softbound. $7.50. Available from Information Branch, Arizona Game and Fish Department, 2222 W. Greenway Rd., Phoenix, AZ 85023, USA.

As more persons while away pleasant moments in the natural areas of Arizona, the likelihood that someone will encounter a venomous reptile increases, especially since Arizona has more venomous reptiles that any other state. For some, such an encounter is a delight, whereas for others, the experience is traumatic indeed. Sensitive to the extremes on both ends, Lowe, Schwalbe and Johnson have published a helpful, well-illustrated, portable guide to the venomous reptiles of Arizona.

The authors introduce the reader to the unique venomous taxa indigenous to Arizona and include definitions of terms used throughout the text. The State of Arizona has long been a pioneer in protecting wildlife and the legal status of the local reptiles is reviewed.

Each species account contains a description, with additional material on size, behavior, toxicity, prey, reproduction, habitat and abundance, distribution, and subspecies where applicable. The section on Gila monsters is particularly impressive and many of the ecological and behavioral observations reflect years of field work.

Introductory sections encapsulate information which treat the biology of elapid, crotalid and rear-fanged snakes. The western coral snake, the seventeen taxa of rattlesnakes and the six rear-fanged colubrid snakes are all covered. The accounts are liberally interspersed with interesting observations, both in the field and captivity, which contribute to a broader perspective regarding these creatures. Each taxon is represented by at least one color photograph and, almost without exception, the quality is superb. Three photographs taken in the field are particularly exquisite: fighting male Gila monsters, copulating Southwestern speckled rattlesnakes, and male Western diamondback rattlesnakes in combat. This latter photograph is one of the finest reptile photographs that I have ever seen. In addition to the 50 photographs, the book is illustrated with line drawings and maps of high quality.

A nicely rendered section with photographs depicting the habitats of Arizona was a nice touch which stimulated me to want to return to Arizona at the earliest moment. The comprehensive final section is entitled "The Bite and Its Treatment" and should prove to be especially helpful to those persons unfamiliar with venomous reptiles.

Systematists should take note that the authors recognize the polytypic nature of the Western diamondback rattlesnake by referring to the Arizona population as *Crotalus atrox atrox* and the taxon on Isla Tortuga as *C. a. tortugensis.*

This is a lively, well-written book in an attractive format which should prove to be a most successful publishing venture by the Arizona Game and Fish Commission. The taxpayers of the state should be commended for supporting this enterprise through voluntary contributions to the Nongame Income Tax Checkoff.

Snakes of Western Australia, by G. M. Storr, L. A. Smith and R. E. Johnstone. 1986. Western Australian Museum (Frances Street, Perth, Western Australia 6000), 187 pp., 5 figs., 24 color plates, soft cover. $19.95 Australian.

This is the fourth in a series of books on the reptiles and amphibians of Western Australia produced by the Western Australian Museum. The stated purpose of this book is to enable the reader to identify the 102 species of snakes known from Western Australia. It accomplishes this with thoughtful organization, excellent illustrations, and a readable style.

The book starts off with four one-page sections: Forward, Acknowledgments, Introduction, and How To Use This Book. The latter section serves as a useful orientation to the reader that may be unfamiliar with taxonomic keys, species descriptions, and range maps. The authors then plunge directly into the systematic treatment of the suborder Serpentes. A one-page summary of the origin of Australian snakes is followed by a very clear and usable key to the families of the snakes of Western Australia. Each of seven families is treated in order, in a consistent format. Genera and species within families are considered in alphabetical order. Virtually all the text falls under these headings: diagnosis, description, distribution, remarks, derivation of name, and references. This is the case for the treatment of families, genera, and species. Taxonomic keys are provided at both the genus and species level. The keys are clear, and they are based on readily accessible external characters. The keys are accompanied by species descriptions that are well illustrated with clear line drawings of both dorsal and lateral views of head scalation. In addition, many descriptions are augmented by one of the 97 color photographs that are found in the plates. Overall, the quality of the color photos is excellent and none are poor. Distribution maps are included with each species description. The volume ends with a one-page first-aid section, a bibliography of more than 135 references, most of which are post-1960, an illustrated glossary, and separate indices for English and scientific names.

This book fully accomplishes its goal of providing a tool with which an interested student can identify the snakes of Western Australia in a field setting or laboratory.

HAROLD K. VORIS

Roosevelt Road at Lake Shore Drive
Chicago, IL 60605-2496, USA •

Amphibians and Reptiles in West Virginia, by N. Bayard Green and Thomas K. Pauley. 1987. xi + 241 pp. University of Pittsburgh Press, Pittsburgh, PA 15260. $29.95 cloth $14.95 paper.

This is a small book, 18.7 x 11.5 cm, that would easily fit into one's daypack or fieldbag. In this respect, the book well serves its second stated purpose, "to provide a manual for naturalists and students who have no previous experience with amphibians and reptiles." The chapters on history, physiography and climatology, how to locate and photograph herps, and collecting and caring for them are very brief and written simplistically — my twelve year-old could understand most of the material in

these chapters. The illustrated keys to adult groups and tadpoles (but not salamander larvae) will identify the most commonly encountered variations in color and pattern; the uncommon variations will be difficult to identify. The species accounts, preceded by descriptions of class and order, are structured similarly with common and scientific names, etymology, description, habitat and habits, breeding, remarks, and range. Range maps are postage stamp in size, with a single dot for each county recorded. The color photographs of adults are arranged as a single set of plates. There is a list of species of special concern (all protected by state law), a glossary, and a bibliography.

The book's first stated purpose, "to place on record a summary of available information concerning distribution, habitat, and seasonal activities of various species" is achieved by just that — brief summaries of distribution, habitats, and breeding biology. The most important contribution of the book is the inclusion of original observations on most West Virginia species. Literature references maintain a common base of information presented among accounts.

Several criticisms need to be mentioned because they detract from the usefulness of this book. The price is the most detrimental problem; I'd hesitate to buy it for just that reason. It has been my experience that non-biologists often equate subspecies with species. Separate subspecies accounts, as found in this book, only reinforce the misunderstanding of that taxon. Little is gained by illustrating distributions with single dots in counties. Authors of state-level faunal books should plot actual location records, thereby allowing a more accurate appraisal of distributional patterns. Cross-checking the literature could have avoided errors such as incorrect etymologies for the genus *Ambystoma* (compare with Tihen 1969) and northern water snake (see Brown 1956). Although most of the color photographs are well done, several (e.g., *Plethodon wehrlei, Rana catesbeiana, Nerodia sipedon, Pseudemys rubriventris*) are washed out and on a faded white background. The red-bellied turtle is obviously dead. I found the use of both inches and metric conversions for ***every*** measurement cumbersome. Total length only is given for salamanders, lizards and snakes, carapace length only for turtles, and snout-vent length for frogs. Most herpetologists report snout-vent lengths for salamanders, lizards and snakes, and plastron length for turtles. There is a short section on Poisonous Snakes and Snakebite, but I couldn't find anything on the latter in it. The bibliography has ***three*** sections: general, literature cited, and works consulted. Finding a particular reference is made difficult by the inclusion of the last section. More attention should have been paid to citation consistence; some authors are listed with full names, others with initials. My overall impression is that this is the first field guide undertaken by this press and that the book was done somewhat hurriedly.

If naturalists and students (and professionals) can afford this book, then it will fill a long-standing void. It is a usable field guide and I highly recommend it to anyone working with the herpetology of West Virginia and the immediate region.

•

Vertebrate Animals of Alabama in Need of Special Attention, edited by Robert H. Mount. 1986. Alabama Agricultural Experiment Station, Auburn University, AL 36830. 124 pp., numerous figures, 102 photographs, softbound. $12.00.

It will be no surprise to biologists familiar with Mount's 1975 treatment of Alabama's amphibians and reptiles to learn that this volume is in the same tradition — a work of exceptional scholarship and quality. This handsome, softbound book represents the combined efforts of participants in a 1983 conference concerning Alabama's nongame wildlife. As Mount notes in the preface, the conference was one of the first steps taken in implementing Alabama's Nongame Wildlife Program. This volume reviews the biology of poorly known or imperiled Alabama vertebrates. In all, 18 fish, 18 amphibian, 26 reptile, 29 bird, and 15 mammal species or subspecies are considered.

Each animal is classified as being poorly known, of special concern, threatened, or endangered. For the poorly known species, insufficient information is available to permit classification, and Mount believes work on these animals should be among the top candidates for research funding. The threatened and endangered classifications follow the federal guidelines, and species of special concern are defined as those that need continued monitoring to assess population trends. Each species account is comprised of brief paragraphs under the following categories: other names, description, range, habitat, life history and ecology, basis for status classification, recommendations, and selected references. The author of each account is identified. Ten southeastern biologists wrote the 43 amphibian and reptile accounts; Mount wrote 11, D. Bruce Means wrote 8, Dale Jackson wrote reviews for five turtles, and the other seven authors each contributed four or fewer reviews.

Five species (the eastern indigo snake, *Drymarchon corais*, and four sea turtles, all federally listed as threatened or endangered) are considered endangered species in Alabama. The Atlantic hawksbill (*Eretmochelys imbricata*) occasionally occurs on the northern Gulf coast and should probably be added to Alabama's endangered species. Two frogs (Pine Barrens treefrog, *Hyla andersoni*, and the dusky gopher frog, *Rana areolata sevosa*), two salamanders (eastern hellbender, *Cryptobranchus alleganiensis*, and Red Hills salamander, *Phaeognathus hubrichti*), three snakes (southern hognose, *Heterodon simus*, black, *Pituophis melanoleucus lodingi*, and Florida, *P. m. mugitus*, pine snakes), and four turtles (Barbour's map, *Graptemys barbouri*, Alabama red-bellied, *Pseudemys alabamensis*, and flattened musk, *Sternotherus minor depressus*, turtles and the gopher tortoise, *Gopherus polyphemus*) are considered threatened in the state. The alligator, two salamanders, three snakes, and four turtles are considered worthy of special concern. The other eleven salamanders, the coal skink (*Eumeces anthracinus*) and five snakes are poorly known in Alabama. Since publication, the flattened musk and red-bellied turtles and the gopher tortoise have gained federal protection.

Except for the sea turtles, most of the amphibian and reptile species accounts are accompanied by a state and national range map. Generally, the ranges are similar to those in Mount's 1975 book, but the Alabama range of the American alligator (*Alligator mississippiensis*) is shown greatly reduced. It is obvious that efforts have been made to update the distribution knowledge of Alabama's herpetofauna. Since Mount's 1975 book, the Pine Barrens treefrog, the one-toed amphiuma (*Amphiuma pholeter*) and the Black Warrior waterdog (*Necturus* sp.) have been added to Alabama's fauna. In addition, the southern dusky salamander (*Desmognathus auriculatus*) is recognized as a valid species.

All fish, amphibian, reptile, and nearly all of the bird and mammal accounts are accompanied by color photographs. The amphibian and reptile photographs, from many sources, are of excellent quality. There are other good treatments of regional threatened and endangered species, for instance, the Florida series. But this book must certainly be counted as one of the best if not the best. I highly recommend this volume to all those interested in preserving the Earth's fauna.

•

Les Gerrhosaurinae de Madagascar. Sauria (Cordylidae), by E. R. Brygoo. 1985. Mém. Muséum Nationale d'Histoire Nat. Paris. Sér. A, Tome 134. 65pp, 18 figs. Price 100F.

Twelve species and 2 subspecies of gerrhosaurine lizards, consisting of two endemic genera, are recognized from Madagascar and the neighboring isles. Each is described in detail, and its distribution indicated on outline maps. Drawings depict either the general topography of the animal and/or enlarged aspects of selected regions of the body essential for proper identification. In spite of the two endemic genera and the 12 species, there has been little diversification on Madagascar in contrast to the species of the same family in South Africa. A key to the species of *Zonosaurus* is provided, lectotypes have been selected for a number of other species, and a new subspecies described.

Snakes of the World, by Chris Mattison. 1986. 190 pp., 100 plates (59 in color plus color frontispiece), 14 figures, 12 maps, 6 tables. 9 1/2 x 6 1/4 x 3/4 inches. Facts on File Publications. $17.95.

Any introductory text about snakes (and herps in general) faces an immediate obstacle in the diversity of experience and education of its intended audience. The needs of a ten-year old with his or her first garter snake are different from those of a college student in a herpetology course or a self-trained but experienced amateur. **Snakes of the World** by Chris Mattison is an interesting summary of snake natural history and taxonomy, but it suffers from some defects of tone in its often self-conscious effort to remain an introduction.

The book consists of nine chapters: What are Snakes?; Size, Shape and Function; Colour and Markings; Reproduction; Foods and Eating; Defense; Ecology and Behaviour; Snakes and Man; and, Snake Families. The contents of these are self-explanatory. The author writes from an admirable ethological perspective, using modern concepts of animal behavior and population ecology to discuss the habits, behaviors and reproductive strategies of typical snakes. (I was pleased to discover no group selection arguments.) Lengths of snakes are given in both English and metric units.

In the first eight chapters, wherein the basic concepts about snakes are elucidated, the anecdotal approach of the bestiary is avoided. Chapter 9 occupies the last third of the book and gives detailed descriptions of the eleven snake families and their genera, with range maps and photographs of representative species. The photographs, many in color, are one of the strongest assets of the book, although they undoubtedly contribute to the relatively high cost considering its size. The information presented is neither too cursory nor too detailed for the average reader. In general, **Snakes of the World** is a satisfactory effort.

My chief complaint about this book, however, is the inconsistency of the author's tone. He has the annoying habit of putting words he thinks are strange or unduly colloquial in quotation marks. Representative examples are: "giant" snakes (p. 19), "tentacles" of *Erpeton tentaculum* and rattlesnake "rattle" (p. 38), "cashing in" (p. 53), snake "design" (p. 96), and, "trade-off" (p. 97). Others are more technical terms, perhaps unfamiliar to the amateur, like "lingual fossa" (p. 32), vertebral "processes" (p. 47) and "ecdysis" (p. 73). In these latter cases, the words are followed by their definitions. Unfortunately, many other equally technical and probably more unfamiliar terms are mentioned in passing, without definition, or are defined parenthetically. These are not put in quotes. Many texts thoughtfully employ quotes or italic or boldface type when introducing new terms; but this must be done consistently and without affectation. Drawing such attention to rattlesnake "rattles" and snake "design" is condescending, even if the latter is supposed to mark a teleological concept.

There are several other defects of varying severity. This book lacks a glossary, a serious oversight for an introductory text. Figure 11 (p. 45), a line drawing of the internal anatomy of a snake, is poor and confuses the reader on two counts: the dorsal view obscures some of the organs, and unless one colors in the drawing, the organ boundaries cannot easily be identified. Plate 39 (p. 62) is a self-proclaimed "simulated photograph" of a *Thamnophis sirtalis parietalis* breeding aggregate. This probably means that a bunch of garter snakes were dumped in a pile and photographed. Even though "this re-creation depicts authenticated facts" (as the closing credits of Wild Kingdom used to say), I would rather see the real article. The author's argument that the so-called Mertensian coral snake mimicry is actually deimatic coloration (p. 53) perhaps needs more justification than he has given. Lastly, only one typographical error was found in the entire text: the caption for Plate 26 (p. 51) has "suberbly" for "superbly."

Snakes of the World fills the need for an intelligent compromise between **The How and Why Wonder Book of Snakes** and **Herpetologica.** It may prove too expensive to use as a college text, and the occasionally condescending tone may put off older or more learned readers. The material is succinctly surveyed and the interpretations up-to-date. I am not strongly against this book, but I am not strongly for it either. Its best audience is probably the interested amateur, high-school age and older.

The Snakes of Australia, by Gerard Krefft. 1984 reprint of 1869 (publ. in Sydney) original. xxv + 100 pp, 12 color plates; clothbound. Price $55.00 Australian

THE COMPLETELY ILLUSTRATED
ATLAS
OF REPTILES AND AMPHIBIANS FOR THE TERRARIUM

Fritz Jürgen Obst **Dr. Klaus Richter** **Dr. Udo Jacob**

Editor, English-language edition: Jerry G. Walls

OVER 2000 PHOTOS — MORE THAN 1500 IN FULL-COLOR

Here is a truly comprehensive and beautiful volume covering all the reptiles and amphibians kept in terrariums plus virtually all the oddballs and rarities any hobbyist (or scientist, for that matter) is likely to ever see or want to know about. Illustrated in full color are hundreds of common and rare reptiles and amphibians, invertebrates, food animals, terrarium plants, environments, and diseases, with hundreds more black and white photos and line drawings. But don't think that this book is just pictures—the authoritative and useful text covers thousands of species, the majority of genera, and hundreds of topics dealing with terrarium care and natural history. The alphabetical arrangement makes it easy to find information on almost any topic you can think of, and you can be sure the information is correct and up-to-date.

The photos represent the work of dozens of photographers in the United States, England, Europe, and South America, brought together to produce the most comprehensive and well-illustrated single volume ever published on terrarium animals. Included is extensive coverage of such popular genera as *Lampropeltis, Elaphe, Anolis, Geochelone,* and *Hyla,* but the true rarities are also well-illustrated, including genera and species most readers will have never encountered before anywhere.

This volume is the perfect answer to the terrarium keeper's dilemma of attempting to find where an animal originated and what type of habitat it requires. It is the obvious first place to look for a solution or a hint to all your questions while having fun looking at the marvelous photos at the same time.

(overseas). Published by Lookout Publications, GPO Box 1405, Brisbane, Queensland 4001, Australia.

This book was the first systematic review of Australia's popular snake fauna, and it covers all 82 species then known, including the 15 marine taxa. For each species, a synonymy and diagnosis are provided, together with descriptive and distributional information on specimens in The Australian Museum in Sydney, where Johann Ludwig Gerard Krefft (1830-1881), a German immigrant, was then curator. Many of the species are figured in the plates, although in most instances only the head is illustrated. Several of the plates depicting a whole animal are quite lifelike and real works of art. Krefft also went to considerable effort to categorize the various venomous species according to their degree of toxicity, through regular experimentation. In all, this is a useful review but with 160 species known as of 1983 it covers only half of Australia's snake fauna yet includes all of the most common or widespread species.

The original book was issued in an edition of 700 copies and only a few copies had colored plates. Understandably, an original is very costly today and a colored copy can bring in excess of $1000. Thus, this reprint fills an important need in making this historically important work available at a reasonable price. I recommend it.

It seems quite inappropriate to critique a book originally published 119 years ago, but a few technical comments on the reprint itself may be in order. In general the facsimile is faithful to the original. The color plates are fair reproductions, although the blues and especially the greens are not nearly as vibrant as in the original. Moreover, the book is printed on a paper having a rough surface that imitates the pattern of cloth. This presents no problem for the text, but it gives the illustrations a false sense of texture that almost resembles scutellation.

I do have one criticism, although some may see it as a quibble. To me, any book advertized as a facsimile ought to be exactly that, so that the user, without access to the original, can work with the reprint in full confidence that no changes have been made. If changes must be made, for technical or financial reasons, they ought to be noted explicitly in the reprint. In *The Snakes of Australia*, for example, all of the captions and numbering on the plates have been reset in type. True, those in the original book were somewhat crude, but in the resetting a few transcriptional errors were made, although in this instance they probably are not of any great importance.

Gray's Monitor Lizard, by Walter Auffenberg. 1988. University of Florida Press, Gainesville, FL. xi + 419 pp. Hardbound. Price $39.00.

This is the remarkable story of a large lizard that for 130 years after its scientific description was known from just three specimens, only one with adequate locality data. In 1976, Walter Auffenberg rediscovered Gray's monitor (*Varanus olivaceus*) in southern Luzon, Philippine Islands, and this book summarizes his seven years of field and laboratory observations. Not often can one person write virtually all that is known of an animal and do it so well.

Gray's monitor inhabits limestone hills with numerous deep crevices and mixed dipterocarp forest at elevations below 500 m. Telemetry indicates the lizards move from the crevices into the trees and are difficult to observe. Its range is confined to seven provinces in southern Luzon and nearby Catanduanes Island, but some localities are within an hour drive from Manila.

Gray's monitor is unique among varanids in that it feed largely on fallen fruit of about a dozen species of trees and has a significant role in dispersing the seeds of some of them. Land snails (largely one species) and hermit crabs are the only other major items of diet. Although it eluded scientists for well over a century, this monitor is well known to inhabitants of the region where it lives, and they eat it regularly. However, the greatest threat it faces is deforestation which destroys both its refuge and its food supply.

These are but a few of the facts gleaned from Auffenberg's book which is a tribute to the author's talents as a herpetologist, ecologist, and all around naturalist. Ten chapters are devoted to the lizard's ecology and life history, all based on the author's research. There are numerous comparisons with other Asian varanids and, in some cases, with other large lizards. Many come from the authors well known studies of the Komodo dragon (*Varanus komodoensis*). I found sections dealing with food, feeding, and interactions with other animals in its habitat specially interesting; those on reproduction and related behavior rather less so. Other chapters are devoted to methodology, morphology, systematics, and conservation. The last contains some cogent comments on problems facing those trying to protect the native biota of overpopulated and economically distressed nations.

The list of literature references is long and covers topics as diverse as tick-host specificity, Tertiary geology of the Philippines, and seed shape as a factor in gut retention. There are numerous good quality drawings and maps; the few photos are not exceptional. Appendices contain annotated lists of plants, birds, and mammals mentioned in the text.

Although in all respects a scientific treatise, this is also quite a readable book. Any biologist contemplating study of vertebrates in a tropical forest setting should find this a most helpful and stimulating book and a model for reporting research results. Except for some whose interests are very narrowly focussed, herpetologists will find it engrossing and useful. One can hope others will do as well with their favorite animals.

The Biology of Australasian Frogs and Reptiles, edited by Gordon Grigg, Richard Shine, and Harry Ehmann. 1985. Surrey Beatty & Sons, 43 Rickard Road, Chipping Norton, NSW 2170, Australia. xvi + 527 pp. $ Aus65.00, $ US59.00.

Herpetology is very much alive in the antipodes. This large and attractive book is a compilation of 63 papers presented at the Australasian Herpetological Conference in August, 1984. Participants came from several nations, but most of the papers are by workers in Australia or New Zealand. Following Ron Strahan's witty opening remarks and Carl Gans' keynote address, "In Praise of Diversity," the papers are grouped in seven subdivisions: Population Ecology, Ecological Biogeography, Reproductive Biology, Phylogeny of Elapid Snakes, Rare and Endangered Species, Husbandry and Snakebite. It is a tribute to the authors and editors that there are really no mediocre papers. With the wide selection offered, only the herpetologist whose interests are highly specialized or narrowly provincial will fail to find something that gets his attention. However, not all herptile groups get adequate treatment. The comparatively rich typhlopoid snake fauna of Australasia is barely mentioned. The pygopodids, Australia's only unique reptile family, are mentioned only with reference to certain endangered and rare species, and the pythons and varanids do not fare much better. Scientific nomenclature generally follows the **Zoological Catalogue of Australia** (Cogger, Cameron and Cogger, 1983) but be advised that the little frogs known as *Ranidella* to Watson and Littlejohn are once again *Crinia* to Roberts and Maxson.

It is obviously not possible to evaluate or even mention more than a few of the contributions, and my selections reflect personal bias. The 12 papers on Australasian elapid snakes include history (Cogger), external morphology (Storr), Chromosomes (Mengden), and amino acid sequences of enzymes and neurotoxins (Tamiya). All basically agree that

antipodean proteroglyphs, including sea snakes, comprise a reasonably homogeneous group quite distinct from the proteroglyphs of Africa, Asia, and America. Within Australasia, however, the number of lineages that can be recognized remains debatable.

This may well be the most current source of information on the biology of the New Zealand herpetofauna. Seven papers are devoted to that nation's unique frogs, lizards, and tuatara. J. H. Gibbons provides a good overview of Pacific island herptile biogeography with special emphasis on Fiji species.

Australia's frogs present some interesting puzzles. Leptodactylids show no less than eight reproductive patterns including that of *Assa darlingtoni* in which eyeless tadpoles find their way to the male's brood pouches, *Philoris frosti* with a free-living but non-feeding tadpole stage, and the unique gastric brooding of *Rheobatrachus silus*. The latter species also presents a cautionary tale for conservationists. At the time of its discovery in 1973, it was reported as abundant; since 1980, no specimens have been seen in the field and the last captive has died. It was protected almost from the time of its discovery, and reasons for its disappearance are a mystery. Meanwhile a new gastric-brooding *Rheobatrachus* has been discovered! Some species of the Australian herpetofauna clearly require protection, however Ehmann and Cogger are quite critical of current legislation and policies that discourage research and alienate amateur herpetologists.

The publishers have spared no effort to make this an elegant book. There are 12 color plates, all excellent, and numerous half-tones, maps, and other graphics. It is also an expensive book but worth the money. Any herpetologist going for the first time to the South Pacific is strongly advised to peruse it. For those who have been there, it will revive memories, while those who live there can point to it with pride.

Handbook of Animal Diversity. Blackwelder, R.E. and G. S. Garoian 1986. CRC Press Inc, Boca Raton, FL. (5) +555 pp., figs, tabs. $165. (outside of US $190).

The preface to this book notes that it "summarizes the entire Kingdom Animalia." Its major sections deal with reproduction, development, structure of the adults, behavior, coloniality, death and classification (down to class level). The plan is fine, but the utility of the book is mainly to specialists who will be reminded of a diversity of topics that might not immediately jump to mind without suffering from the excessive omissions and errors. Furthermore, the treatment includes redefinition of many terms. The very scope suggests the unfortunate fact that no two zoologists could possibly have carried out this task because human limitations will inevitably make any treatment outdated.

Hence this volume is disappointing; indeed, one wonders what the publisher meant to achieve by pricing it at this level and not noting that there are almost no references past the 1970s, and most of the texts are referred to by editions a decade or more out of date. (Whatever personal judgment, it might have been nice to mention cladistics.) Diversity remains an issue of concern to all of us as teachers and as researchers. There is clear merit to having a single volume summary and perhaps a two-person judgment on standardization of terminology. However, such treatment, at the least, requires review of the manuscript by specialists (none such are acknowledged).

Looking At Vertebrates: A Practical Guide to Vertebrate Adaptation, by Elizabeth Rogers. 1986. Longman. Distributed by John Wiley & Sons. xi + 195 pages. Photographs and sketches, cloth. $24.95.

This attractive book is apparently a hard-bound teaching manual, intended to provide a laboratory companion to the study of vertebrate biology. It was produced in the U.K. and has not been modified for the U.S. market, accounting for the usage mainly of European species. The book requires demonstration materials on monotremes but not on lungfishes or *Polypterus*, even though these animals might be much more easy to obtain. (Fishes are lumped together and several "designs" are contrasted; this causes one to dissect teleosts and elasmobranchs in parallel.) The approach is one of allowing the examination of numerous species, some as demonstrations and some as hands-on dissection material. Utilization of supplementary forms, such as road kills and commercially obtained specimens, is repeatedly suggested as keeping to a minimum the number of animals that need to be killed. For each group of organisms, pictures and general comments are followed by specific details organized by features. The text is written in the Socratic fashion, asking questions which are either answered immediately or referred to again on subsequent pages.

The basic idea is good, and this may be the sort of nook that a teacher of comparative anatomy may wish to have available in order to extract ideas selectively. However, the treatment is insufficient in that there are numerous errors and approaches which should not be presented unfiltered to undergraduates. Most important is a rather typological approach, for instance "the frog" is assumed to be typical for all frogs, and all salamanders are assumed to have four limbs. Even when there are allusions to interspecific differences, their nature is often left unclear. An even more critical item is the emphasis on adaptation as the exclusive source of diversity.

The material is organized in strictly classificatory scheme, but not even lip service is given to phylogenetic and developmental influences. Also, there are substantial small mistakes, explicit or by implication, such as that the larva of amphioxus has an atrial pore (a photo shows an arrow although the larva lacks an atrium), that the blastopore forms the anus, that *Branchiostoma* has a head, that gill ventilation in lampreys has a ciliary component, and that the integumentary water barrier of reptiles is proportional to the thickness of the keratin layer.

The approach of the volume is pleasant, but the text requires substantial modification to make it acceptable.

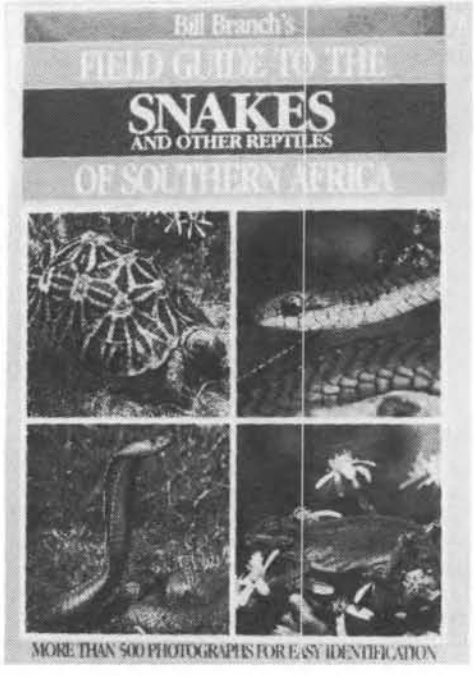
Zoological Bibliography of Turkey: Pisces, Amphibia, Reptilia, by Ibrahim Baran, Brian Coad, Mustafa Kuru. 1986. Published and Edited by Max Kasparek, Heidelberg, F. R. Germany. No price stated.



This bibliography will be extremely useful to the taxonomists and zoogeographers since it fills a major gap found in other similar publications. The land of Turkey can be classified either as part of Europe of part of various subdivisions of Asia, hence most reviews of the zoological literature of Turkey are inadequate. The fishes are listed separately (753 references) and the list includes an appendix of 11 papers on fossil fish. The reptiles and amphibians are listed together. This list is subdivided into 428 references specific to Turkey and 100 references specific to neighboring areas.

Concerning the herpetological references, this bibliography appears to be thorough, unlike other recent publications claiming to provide reference lists, for example, Welch's **Herpetology of Europe and Southwest Asia.** Welch included almost none of the many dozens of Turkish publications which are listed in the reviewed bibliography. Also, the authors have done an excellent job scanning the literature of the Soviet Union journals.

NEW HERP BOOKS

Field Guide to the Snakes and Other Reptiles of Southern Africa

by Bill Branch

Nearly 400 species of reptiles are found in the southern African region comprising So. Africa, Zimbabwe, Mozambique, Nambia, Botswana, Lesotho, and Swaziland. Over 525 color photos have been arranged into 96 color plates showing the key identifying characteristics of each species. Each species is grouped with similar-looking species cross-referenced to the relevant species account for easier field identification. The photos show species and notable sub-species and color variations.

Each species identification includes the size range, a discussion of biology and breeding, habitat and range. Where subspecies occur, these are described and their distributions given. Each species account is accompanied by a distribution map. Keys to the families, line illustrations, explanatory notes and a glossary make this a usable reference for all.

I.S.B.N. #0-88359-023-9 • • • • L.C. #*88-71278

Size 5¾" x 8¼" - 326 Pages, 528 color photos, 409 distribution maps. Hardcover with dust jacket **$29.95**

Reptiles of Southern Africa

by Rod Patterson, Photography by Anthony Bannister

A handsomely illustrated guide to 90 of Southern Africa's most fascinating reptile species. 238 excellent color photos compliment the text that describes the various species. A chapter on snake bite covers prevention, first aid and treatment. There is a rather extensive, illustrated chapter on keeping reptiles in captivity.

128 pages 8½" x 11" hardboard cover **$39.50**

The Poisonous Snakes of India

Compiled by Joseph Ewart - 1985 Reprint of the scarce 1878 Classic Work. I.S.B.N. #0-88359-019-0

The original publication was limited to 1000 copies for use by British Indian Empire officials. 64 pages with 20 color plates. The book also give details on snake bite treatment as it was practiced at the time.

Hardbound 7½" x 10" Import **$39.50s**

Reptiles and Amphibians of Australia

By H.G. Cogger I.S.B.N. #0-88359-021-2

In this book Dr. Cogger has set out to provide for the first time in nearly a century, identification keys to the entire Australian herpetofauna - frogs, crocodiles, turtles, lizards and snakes. These keys, together with over 880 photographs (230 in color) of living reptiles and frogs, 830 distribution maps, line drawings, definitive test and selected references, combine to provide a unique and comprehensive guide to these important and fascinating animals.

This fourth edition of what has, since first publication in 1975, become a classic in its field has been revised and expanded to encompass the taxonomic changes which have occurred since publication of the Third edition in 1983. A 28 page appendix has been added with changes in nomenclature and taxonomy that have occurred since July 1982. All photographs are fully cross-referenced to the text.

— Price — **$59.50s**

Reptile Cages

FOR THE AMATEUR
OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door is inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $33.95
24" Wide, 12-1/4" High, 12-1/2" Deep
250 sq. in. Floor Area, Single Vent

36" Reptile Cage $58.95
36" Wide, 18" High, 19" Deep
580 sq. in. Floor Area, Double Vent

Prices include freight charges and are shipped via UPS. Institutions, zoos and dealers are invited to write on letterhead for quantity prices.

Although the individual species contributions and their authors have been cited, the **Handbuch der Reptilien und Amphibien Europas**, edited by Wolfgang Böhme, should have been both cited and mentioned in the preface. This excellent encyclopedic series, which completely includes Turkey, had already covered all lizard families and genera (except *Lacerta* and *Podarcis*) in Volume 1 (1981) and *Lacerta* in Volume 2 (1984), within the time framework to have been included in the current bibliography. Volume 3, *Podarcis*, was published in 1986, and the remaining volumes on snakes, turtles, salamanders and frogs are being prepared. Böhme's Handbuch is exceptional in that it thoroughly treats the Turkish literature.

SCOTT M. MOODY

Athens, OH 45701, USA •

Neotropical Ornithology. American Ornithologists' Union, Ornithological Monographs No. 36, 1985. xii + 1041 pp + 8 color plates, cloth bound. Obtainable from Frank R. Moore, Department of Biology, University of Southern Mississippi, Southern Station Box 5018, Hattiesburg, Mississippi 39406, USA. $70.

It may seem out of place to review an ornithological publication in *Herpetological Review*, but there are several papers in this well-produced volume that are pertinent to herpetologists, especially those persons working in the neotropics. This volume, edited by P.A. Buckley, Mercedes S. Foster, Eugene S. Morton, Robert S. Ridgely, and Francine G. Buckley, contains 63 papers. Except for an introduction by Thomas R. Howell and a final overview by Kenneth C. Parkes, the papers are grouped into sections — new taxa (5), zoogeography and distribution (11), systematics (9), evolution (10), community and population ecology (8), breeding biology (3), and conservation (5).

The papers that will be of major interest to herpetologists are in the sections on zoogeography, evolution, and ecology. Joel Cracraft provides a historical overview of the neotropical avifauna with emphasis on areas of endemism. Jurgen Haffer presents a thorough discussion of avian zoogeography of the neotropical lowlands with emphasis on climatic-vegetational changes in the late Tertiary and Holocene. These two papers provide an excellent review of the biogeography of the neotropical avifauna. More specific zoogeographic studies of interest to herpetologists include Helmut Sick's evidence for Andean-Patagonian elements in the avifauna of southeastern Brazil and Francois Vuilleumier's biogeographical analysis of the avifauna of the Patagonian forests.

Other papers of interest include P.R. Grant's discussion of the influence of climatic fluctuations in the Galapagos Islands on Darwin's finches and Lester L. Short's comparison of neotropical and African radiations of barbets and woodpeckers. The effects of habitat alteration on species composition and abundances are presented effectively in two papers — Stephen L. Hilty's work on Colombia and John H. Rappole and Eugene S. Morton's study in southern Veracruz, Mexico.

RECENT PUBLICATIONS RECEIVED

Pelycosauria. Reisz, R. R. 1986. Handbuch der Paläoherpetologie 17A 102pp, 43 figs. In English. Gustav Fischer Verlag, Stuttgart, New York.

A comprehensive review and update of an important and interesting order of primitive reptiles.

Catalogue of the Neotropical Squamata. 1986. Part 1 Snakes, by J. A. Peters and R. Donoso-Barrios (347 pp), Part 2 Lizards and Amphisbaenians by J. A. Peters and B. Orejas-Miranda (293 pp) both with new material by V. E. Vanzolini. Price $29.95. Smithsonian Institution Press, 955 L'Enfant Plaza, Suite 2100, Washington, D.C. 20560.

Originally published in 1970, this new version includes revisions, additions and other changes from 1969 to 1984. Indispensable to herpetologists working with neotropical material.

Proceedings of the 1985 Workshop on Care and Maintenance of Natural History Collections, edited by J. Waddington and D. M. Rudkin. Life Sciences Miscellaneous Publications of the Royal Ontario Museum, 100 Queen's Park, Toronto M5S 2C6, Ontario, Canada.

A bit of something for everybody involved in museum curatorial work.

Manual of Exotic Pets - Revised Edition 1985. Edited by J. E. Cooper, M. F. Hutchinson, O. F. Jackson & R. J. Maurice. Published by British Small Animal Veterinary Association, 5 St. Georges Terrace, Cheltenham, Glos. GL50 3PT, England. 224 pp., illustrated and indexed. £15.75 (includes postage).

The Manual of Exotic Pets fills the needs of professionals and amateurs alike. It is well written and readable by people of all levels of expertise from hobbyists to veterinarians. The current state of the art is described in considerable detail in 25 chapters written by more than 20 contributors.

The book is divided into four main sections which deal with Mammals, Birds, Reptiles and Miscellaneous. The last category has chapters on Amphibians, Ornamental Fish, Invertebrates and Legislation. One gets the feeling that this book was written for Europeans, especially British readers, since it goes into such detail about their laws. Still, there is much to be learned about the care and treatment of exotic animals which readers on both sides of the Atlantic will enjoy and benefit from.

The section on Reptiles has separate chapters on Chelonians, Crocodiles, Lizards and Snakes. Each of them deals with Anatomy, Housing, Feeding, Handling, Sexing, Reproduction, Diseases (including parasites and nutritional disorders) plus details on Anesthesia and Surgery. There is also an Addendum on Anesthesia, Chemotherapy, Hematology and Blood Chemistry for Lizards and Snakes. It lists all of the different antibiotics and other drugs and their correct doses.

The authors of the chapter on Chelonians explain that the words tortoise, turtle and terrapin vary according to whether one is talking to a British, American or Australian herpetologist! To the British the terrestrial chelonian is a tortoise, a freshwater chelonian a terrapin and a marine chelonian a turtle. Australians call some terrapins tortoises while to the Americans everything is a turtle! After such a splendid beginning they lapse into terms of reference which are unfortunately parochial. Newly hatched chelonians, they say, are as big as a 50p piece, hardly an adequate term of reference for the non-British reader. I was impressed, however, by the extensive bibliography which follows each chapter and which is more international in scope than the above.

The section on Amphibians is concise and informative. After general considerations the author describes suitable housing, feeding, handling, and behavior and goes into sexing and reproduction. Under diseases and clinical conditions there are references to bacterial, viral, fungal and parasitic diseases and traumatic injuries. There are also suggestions for treatment. Considerable detail is given to management, drug administration, anesthesia, etc., complete with dosages, plus techniques for euthanasia and a small section on surgery.

The book is well illustrated throughout and includes tables, diagrams, photographs and even radiographs of animals like toads and lion fish!

There are other chapters on Chinchillas, Chipmunks, Gerbils, Guinea Pigs, Hamsters, Hedgehogs, Rabbits, Rats and Mice, Deer, Ferrets, Primates and Birds. All in all, if you or your family are into strange pets, or you are a practicing veterinarian, I believe that it is a worthwhile book to have on your library shelf.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology, and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations and photographs. Manuscripts submitted must be typed, double spaced, on 8.5X11 inch paper, and should be sent in duplicate. We encourage submissions on Macintosh disks, though we can also work with TEXT files submitted on IBM and compatible floppies. **Herpetological Review** is composed on a Macintosh SE using Microsoft Word, which accepts files from several other word processor applications. Format your documents full-page width; we will fit to **HR** format.

Unpublished photographs of an unusual nature or of uncommon amphibians or reptiles may also be submitted. These should be 8X10 inches black and white, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled lightly on the back of each print. Return of unsolicited photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs solicited by the Editor will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. Herpetological Review will accept commercial advertising. Rates and copy information are available from the advertising manager. Fully formatted ads may be provided on Macintosh disks in several Draw or Paint formats. Contact the managing editors for details. All ads are accepted at the Editor's discretion.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1988

Student member	$20.00*	Sustaining member	$50.00*
Regular member	$27.00*	Contributing member	$75.00*
Institutional	$50.00*		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Herpetological Review

Volume 19 December 1988 Number 4

SSAR BUSINESS

31st ANNUAL MEETING HELD AT UNIVERSITY OF MICHIGAN

The 1988 Annual Meeting of the Society for the Study of Amphibians and Reptiles was held jointly with the Herpetologists' League, American Society of Ichthyologists and Herpetologists, the American Elasmobranch Society, and Early Life History Section of American Fisheries Society. Local Committee Chair Gerald R. Smith hosted a large meeting of herpetologists and ichthyologists from many countries on the historic campus of the University of Michigan in Ann Arbor in celebration of the 75th anniversary of *Copeia*.

Board of Directors' Meeting

The annual meeting of the SSAR Board of Directors was held on 24 June under the chairmanship of Society President Hugh R. Quinn. All Board members and most editors were present plus many committee chairs and other SSAR members. The Board met for approximately 6.5 hours and reviewed annual reports submitted by all officers, editors, committee chairs and coordinators. The appointment of Robert D. Aldridge to the position of Publications Secretary was approved by the Board. Decisions of the Board were announced at the annual business meeting of the Society and are described in the following section.

Business Meeting

A. Call to Order

President Hugh Quinn convened the 1988 business meeting of the Society for the Study of Amphibians and Reptiles at 1806 h on 26 June in the Vandenberg Room of the Michigan League on the campus of the University of Michigan.

B. President's Report

President Quinn welcomed the assembled members and announced that the Society's financial outlook has improved significantly over the past year. He noted that *Journal of Herpetology* Editor Rodolfo Ruibal has submitted his resignation effective September 1988 and a search is being conducted for his replacement. *Herpetological Review* Editor Martin Rosenberg notified the SSAR Board of Directors that he will be resigning at the end of 1989. Kraig Adler, Editor of *Contributions to Herpetology*, also informed the Board of his intent to resign after publication of the Gloyd and Conant monograph "Snakes of the *Agkistrodon* Complex" in 1989. A search has begun to replace these long-serving editors. President Quinn asked that those interested in the positions contact him at their earliest convenience.

The use of desktop publishing by the Society was reviewed by President Quinn. He noted that the soon-to-be-published index to the Geographic Distribution Section of *Herpetological Review*, 13 pages in the March 1988 issue of *Herpetological Review*, SSAR letterhead, and this year's accounts for the *Catalogue of American Amphibians and Reptiles* were prepared using desktop publishing techniques. Considerable financial savings (40-50%) have resulted from these changes.

President Quinn noted that the 1989 meeting of Society for the Study of Amphibians and Reptiles will be held in conjunction with the World Congress of Herpetology during 11-19 September at the University of Kent in Canterbury, United Kingdom. He encouraged members planning on attending the World Congress to get air travel quotes from both of the official travel agents for World Congress, EcoSafaris and Holbrook Travel.

C. Treasurer's Report

Treasurer Doug Taylor announced that the Society is financially sound but noted that membership has plateaued since 1984. SSAR membership has fluctuated between 2,243 and 2,322 since that time. As the result of inflation, our budget has not been able to increase due to increased expenses. Taylor estimated expenses for 1988 to be $96,764 with an estimated income of $96,959, leaving a balance of $195. He noted that $9,000 was placed in an investment fund last year as a result of income received from the life membership program. These and other investments are being managed by James Christiansen, Chair of the Long-range Planning Committee.

Taylor announced that the Board of Directors approved the appointment of a Membership Secretary who will be responsible for a marketing campaign for next year. The Treasurer noted that Society book sales have been and continue to be a major source of revenue. We, however, still have a limited number of pages which can be published in the *Journal of Herpetology* and *Herpetological Review* with our current budget structure. As a result, it has become necessary to increase dues as follows:

Student Member	$25
Regular Member	$35
Sustaining Member	$50
Contributing Member	$75
U.S. Institutions	$60
Non-U.S. Institutions	$65
Life Member	$600

Life membership dues can be paid in three consecutive annual installments of $200. Other dues can be prepaid for up to three years. These increases will permit the dues structure to be maintained for some time.

D. Committee Reports

1. Kennedy Award

The Kennedy Award is given to the author of the best student paper published each year in the *Journal of Herpetology*. President Quinn announced that Charles C. Peterson of the Department of Biology at the University of California in Los Angeles received the 1988 award for his paper entitled "Thermal relations of hibernating painted turtles, *Chrysemys picta*" (*J. Herp.* 21:16-20).

2. Grants-in-Herpetology

Grants-in-Herpetology Committee member Dale Belcher announced that 16 proposals were received in the graduate student category and two were submitted in the conservation research area. No proposals were received in either the zoo or regional society categories. The committee recommended and the Board approved the award of grants to the following proposals for 1988: **Graduate Student Research in Herpetology:** Marion Preest, Section of Ecology and Systematics, Cornell University, Ithaca, New York, "Metabolic costs of feeding by the lizard *Scincella lateralis*," and Lyndon Ruhnke, School of Biological Sciences, University of Nebraska, Lincoln, Nebraska, "Hybridization of the leopard frogs *Rana pipiens* and *Rana blairi*." **Herpetologically Oriented Conservation:** Dawn S. Wilson, Biology Department, University of South

Florida, Tampa, Florida, "Activity patterns, home range size, and burrow usage of juvenile gopher tortoises (*Gopherus polyphemus*)."

3. Nominating Committee
President Quinn announced the following board-approved slate of candidates were presented by the Nominating Committee: **President Elect:** William S. Brown and Tom R. Johnson. **Director (representing general membership):** James L. Christiansen and Arthur C. Echternacht. **Director (representing zoo and aquaria membership):** Dale Belcher and Donal Boyer. Quinn asked for nominations from the floor for each of these positions. There being none, nominations were closed. The ballot will be mailed to SSAR members via first-class mail during the fall. The deadline for submission of ballots will be 15 December 1988.

4. Resolutions
President Quinn presented the following resolution of thanks prepared by Resolutions Committee Chair George Pisani:

Whereas, the following persons have devoted many hours to advancing the goals of the Society for the Study of Amphibians and Reptiles; and,
Whereas, several of these people have an especially long and distinguished record of service to the Society; and,
Whereas, the Society is most appreciative for the help and guidance received from all these persons; therefore,
Be it resolved that the Society for the Study of Amphibians and Reptiles express sincere thanks to the following persons who relinquished positions at the close of 1987:

Norman J. Scott, Jr. ..... President
Sherman Minton .... Immediate Past President
Henri C. Seibert ..... Treasurer
Douglas H. Taylor ..... Publications Secretary
John L. Behler ..... Director
Harold A. Dundee ..... Director
Kraig Adler .... Chair of Nominating Committee
William S. Brown ..... Chair of Conservation Committee

E. Other Business
President Quinn asked if there was any old business to be discussed. There being none, Quinn asked if anyone had new business to present. Vic Hutchison announced that Holbrook Travel has offered to provide eight half-rate fares or four full-rate fares to support student travel to the World Congress for each 100 regular airline tickets booked through the firm.

F. Transfer of Gavel and Adjournment
President Quinn asked President Elect Henri Seibert to come forward. Quinn, in keeping with the tradition of SSAR, transferred the historic SSAR gavel to Seibert. The President-elect noted that he accepted the gavel with a great deal of pride and acknowledged the honor which was being bestowed on him. He announced that his term as President does not begin until 1 January 1989 and that he expects all problems to be solved and all positions to be filled so he can have a peaceful year. He expressed his hopes to see everyone in Kent next year at the World Congress. Seibert declared the meeting adjourned at 1925 h.

Respectfully submitted,
James S. Jacob
SSAR Secretary ●

SSAR NEEDS MAC-TYPISTS

Our earlier search (see the June issue of *HR*) for a desktop publishing managing editor brought forth several volunteers, one of whom was selected to direct *HR's* transition to this new technology. We are now in need of volunteers to input raw copy from manuscripts (mailed to them by the managing editor) onto their own Macintosh computer (MacPlus with either MacWrite or Microsoft Word 3.01). Since each volunteer would be expected to input several articles over the course of a year, the time commitment will be only several hours per month. The discs would then be sent to the managing editor for formatting and final printing.

Interested? Please contact the editor by mail or telephone (216-368-3558). ●

IN MEMORIAM

NORMAN BAYARD GREEN (1905-1988)

Norman Bayard Green, known as "Bike" to friends, died in Huntington, West Virginia, on 23 May after a long period of declining health. Bike was an acclaimed herpetologist, a steadfast member of the Society for the Study of Amphibians and Reptiles (SSAR) and best known for his studies of the reptiles and amphibians of West Virginia. He was SSAR's second president (then called chairman) 1968-69 and served as Publications Secretary for American Society of Ichthyologists and Herpetologists 1952-64.

Born 15 November 1905 in Bloomington, Maryland, N. Bayard Green received his B.S. degree (Cum Laude) from Davis and Elkins College in 1926 and his M.S. degree from West Virginia University in 1931. He taught at Elkins (WV) High School 1926-38 after which he joined the faculty at Marshall University (then Marshall College). Bayard resumed graduate work at The Ohio State University where he studied under Charles F. Walker, completing a Ph.D degree in 1952 with a dissertation on life history of *Pseudacris brachyphona*. He continued on the Marshall faculty where he headed the zoology department until 1965, served as dean in 1968, and retired in 1971. Bayard authored more than

Computerize Your
Field Notes and Collections

GECKO is a computer program for managing field notes and collections.

GECKO will allow you to:
Record genus, species, subspecies, number, locality, county, state, collector or observer, collection number and comments. Family, order and class are entered automatically.
Extract data for viewing, editing or printing by any combination of the above, e.g. iguanid lizard localities for Inyo Co, CA or all herps seen in Texas from June through August.
List data by order of entry, by date or phylogenetically.
Copy selected records to files for use with spreadsheets, word processors or data base programs.
Count number of species for all or part of the data base, e.g. number of species for 1988 or number of species of *Hyla*.

GECKO is very powerful, yet uses simple screen menus. It incorporates a master species list and is sold with your choice of the U.S. and Canadian list of herps, birds or mammals. Other species lists can be purchased separately and merged into a comprehensive list of terrestrial vertebrates. Lists can be easily edited to accommodate taxonomic changes or new species.
GECKO runs on IBM PCs and compatibles with 320K RAM and DOS 2.0 or later. $75 + $3 shipping. California residents add 6% tax. Please specify species list to be included. Additional lists are $25 each. Similar programs which use common names are available for all terrestrial vertebrates.

Sandpiper Software 153 Michele Circle, Novato, CA 94947

forty scientific publications on amphibians and reptiles and recently (1988) co-authored with his former student, Thomas K. Pauley, a field guide to the "Amphibians and Reptiles of West Virginia" (241 pp). Over a period of 30 years he compiled and curated the largest herpetological collection for the State of West Virginia.

Although I joined the Marshall faculty three years after Bike had retired, he maintained such an active interest in herpetology that I soon came to know him as well as my teaching colleagues. In spite of the 40 years that separated our ages, we developed a close friendship. Bike's reputation as an outstanding teacher became very obvious to me from numerous comments from faculty and former students. Up until his health failed, he often presented lectures filled with anecdotes on Appalachian herpetology to community groups. These presentations always reflected a remarkably broad knowledge of natural history and a devotion to conservation.

Perhaps Bayard Green's most outstanding quality was his sincere generosity. When I arrived at Marshall, as a stranger to the Appalachian region, I was struck by his enthusiasm to share his wealth of information on West Virginia herpetology and his personal library, which included much unpublished work. There was never a trace of guarded or protective attitude which sometimes develops in herpetologists after years of "niche" competition. Typical of his intellectual curiosity and quiet confidence, in conversation Bike was likely to ask as many questions as he answered. Thanks to his expertise, my knowledge of Appalachian amphibians and reptiles grew quickly.

As Bike and I attended annual SSAR meetings together (1976-1981), I became acquainted with some of his friends and fellow officers of SSAR. Several of these individuals later confided to me that the SSAR may not have survived its tumultuous transformation from the Ohio Herpetological Society (OHS) had it not been for Bike's leadership and ability to make some very difficult and unpublicized decisions at a critical time. His devotion to the Society for the Study of Amphibians and Reptiles began in its early OHS phase in 1962. Few would ever know the significance of his real contributions to the society due to his quiet and modest nature. Many of us have lost a good friend and the herpetological community has lost a true professional.

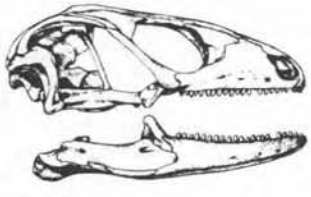
NEWSNOTES



GRADUATE AND POST-GRADUATE RESEARCH GRANTS

The Edumund Niles Huyck Preserve and Biological Research Station announces the 1989-90 competition for research grants (max = $3,500) for biological research for investigations that utilize the resources of the Preserve. The 2000 acre Preserve is located in a hanging valley on the Helderberg Plateau, in the towns of Rensselaerville and Berne, 30 miles southwest of Albany, N.Y. Habitats include northeast hardwood-hemlock forests, conifer plantations, old fields, permanent and intermittent streams, 10 and 100 acre lakes and a 150 ft waterfall. Facilities include a wet and dry lab, small library, and six houses/cabins for researchers. Deadline = 1 February 1989. Application material may be obtained from Dr. Richard L. Wyman, Director and Resident Biologist, E.N. Huyck Preserve and Biological Research Station, P.O. Box 188, Rensselaerville, NY 12147, (518) 797-3440. ●

SPANISH HERPETOLOGICAL ASSOCIATION

The Asociación Herpetológica Española (Spanish Herpetological Association) was founded in 1984 with the goals of study and conservation of Spanish amphibians and reptiles. The headquarters of the Association is the National Museum of Natural Sciences, Madrid. Since 1986 the Association has published the journal *Revista Española de Herpetología*, which is oriented toward studies of Mediterranean region herpetology. The Association holds an annual meeting with scientific paper and poster presentations; the fourth annual meeting will be in Madrid in December, 1989.

Annual dues (which includes subscription to the journal) are $28.00 US (individuals and institutions). Back issues of *Revista Española de Herpetología* (Volume 1, 1986; Vol. 2, 1987; Vol. 3, 1988) are available for $28.00 US per volume. Membership dues and orders for back issues (payment in US Dollars) can be sent to C. J. McCoy, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, 4400 Forbes Ave., Pittsburgh, PA 15213. ●

Phylogenetic Relationships of the Lizard Families

ESSAYS COMMEMORATING
CHARLES L. CAMP

Edited by Richard Estes and Gregory Pregill. Using modern analytical methods of phylogenetic systematics, this is the first comprehensive treatment of the relationships among lizard families to appear in over 50 years. In chapters by the leading experts on particular squamate taxa or anatomical systems, it brings together a vast body of information intended both for systematists and for biologists who know the value of interpreting organismal biology and evolution against a historical background. Illustrated with some 180 drawings and photographs. 648 pages. $75.00

Stanford University Press
STANFORD, CA 94305

HERPETOLOGY COMPUTER NETWORK

The Herpetology On-line Network has been established in Philadelphia as the first computer-based messaging system to connect the herpetological community. Any communicating computer or terminal can connect with one of Herp-Net's six lines by dialing the primary **access number: (215) 464-3562** 24 hours per day. There are no fees to access Herp-Net.

Those interested in the study, breeding, or conservation of reptiles or amphibians can meet others on-line, ask questions, compare research, discuss the current literature, and exchange files. It is a great way to learn what others are doing in the field of herpetology.

Although currently in full operation as a messaging system, Herp-Net would still like to gather as much information as possible to provide a national resource of herpetological information. This would include an up-to-date listing of all local herp groups in North America, timely news and information, as well as the full text of newsletters from as many local groups as possible.

For more information or submission of news, please write to the Herpetology On-Line Network, P.O. Box 52261, Philadelphia, PA 19115, USA. ●

WISCONSIN HERPETOLOGICAL WORKING GROUP

The Wisconsin Herpetological Working Group, established in 1986, is an association of Wisconsin herpetologists, biologists, and naturalists that advises the Wisconsin Department of Natural Resources on conservation issues, research and management priorities, and proposed regulations. It also seeks to educate the general public about amphibians and reptiles and to provide members with information about current research activity within the state. Meetings have been held semi-annually. Further information may be obtained from chairperson David Ross, Wisconsin River Power Company, P.O. Box 50, Wisconsin Rapids, Wisconsin 54494. ●

BIOLOGY OF PLETHODONTID SALAMANDERS

Dr. Stephen G. Tilley of Smith College will teach a course on "Biology of Plethodontid Salamanders" at the Highlands Biological Station during the period 10 July-4 August 1989. The course will include lectures, laboratories, and field studies emphasizing systematics, ecology, and evolution of plethodontids. Credit (5 semester hours) is available through either the University of North Carolina at Chapel Hill or Western Carolina University. The course may be taken without credit. For further information and application forms write: Highlands Biological Station, P.O. Box 580, Highlands, NC 28741, USA. ●

IGUANA MANAGEMENT PROJECT

The Iguana Management Project, with previous headquarters in Panama, has been relocated to Costa Rica, effective October 1988. The Project is now administered by the Pro Iguana Verde Foundation. The core research area is located in the Wildlife Refuge La Avellana (near Orotina) in the buffer zone of Biological Reserve Carara. The office in Costa Rica is located in Heredia.

The Pro Iguana Verde Foundation will continue its activities in Panama as they relate to the projects initiated in Cabuya de Anton, Chupampa and Llano Grande de Ocu. The Costa Rican mailing address is: Fundacion Pro Iguana Verde, Apartado 1501, Heredia, Costa Rica. Tel. (506)37-1027.

VOLUNTEER PROGRAM AT AMNH SOUTHWESTERN RESEARCH STATION

Approximately 20 volunteer positions are open in 1989 at the Southwestern Research Station of the American Museum of Natural History in Portal, Arizona. The volunteer program is run annually and offers students in the biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging at the Station are provided to volunteers in exchange for four hours per day of routine work chores, with the remaining time available for research activities.

Volunteers are needed between 10 March and 1 December and are appointed for part of this period, with a minimum appointment of six weeks. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Applicants for positions from March through May should submit forms by 15 February, summer volunteers, June through September, by 1 April. The program is open to both undergraduate and graduate students, who may pursue their own research projects.

For application forms, write: Resident Director, Southwestern Research Station of The American Museum of Natural History. Portal, Arizona 85632, USA. (602) 558-2396. ●

ALBERT SCHWARTZ HERPETOLOGICAL COLLECTION

Schwartz's extensive collection of amphibians and reptiles from the West Indies has been deposited in the Museum of Natural History, The University of Kansas, Lawrence, Kansas 66045-2454. As the collection is catalogued and integrated into the museum's collection, specimens will be available for study and loan. ●

MEETINGS

SYMPOSIUM ON VERTEBRATE BIOGEOGRAPHY AND SYSTEMATICS

The Zoologisches Forschungsinstitut and Museum Alexander Koenig will host the International Symposium on Vertebrate Biogeography and Systematics in the Tropics. The meeting will take place 5-8 June 1989. A substantial proportion of the presented papers will relate to amphibians and reptiles. For further information, contact: Dr. Gustav Peters, Vertebrate Symposium '89, Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 150-164, D-5300 Bonn 1, West Germany. ●

WILDLIFE REHABILITATION SYMPOSIUM

The National Wildlife Rehabilitators' Association will hold its 8th annual symposium on 22-26 March 1989 at the Grand Hotel in Anaheim, California. Topics will include: veterinary advances in wild species; rescue, restraint and handling techniques; avian, reptile and mammal treatment and biology; captive breeding; wildlife urbanization; post programs; administration and project fundraising. Concurrent presentations will be offered for beginning, advanced and professional levels of expertise. Professional sessions will be limited to veterinarians and medical professionals. Those interested in submitting manuscripts contact: Richard H. Evans DVM.MS., NWRA Program Chair, P.O. Box 7673, Laguna Niguel, CA 92677, (714) 831-1178. For other information or registration materials contact the NWRA Host Committee at the above address. ●

FEATURES

CONSERVATION OF HERPETOFAUNA IN BRITAIN AND IN RELATION TO MAINLAND EUROPE

With His Royal Highness the Duke of Edinburgh, President of the World Wide Fund for Nature International (WWF) and Vice-President of the International Union for the Conservation of Nature and Natural Resources (IUCN) as Patron, the first World Congress of Herpetology is to be held in the UK at Canterbury in 1989. Conservation of amphibians and reptiles will be a strong underlying theme.

Three of the societies co-hosting the World Congress are involved with practical conservation of herpetofauna and their habitats in Europe. They are (alphabetically) the British Herpetological Society (BHS), Fauna & Flora

Preservation Society (FFPS) and Societas Europaea Herpetologica (SEH). Like the American Society of Ichthyologists and Herpetologists in the USA, they are, as non-governmental organizations (NGOs), members of IUCN (Headquarters: Gland, Switzerland). The BHS is a national member of IUCN and the FFPS and SEH are international members. The Jersey Wildlife Preservation Trust, the Zoological Society of London (another Co-host of the World Congress) and the British Ecological Society are also members.

IUCN's Conservation Monitoring Centre is situated in the UK at Cambridge, where Dr B. Groombridge (Compiler of the *Amphibia-Reptilia Red Data Book)* is based, and at Kew Gardens in London. A co-chairman of the IUCN Species Survival Commission (SSC) Tortoise and Freshwater Turtle Group (also director of the first World Congress of Herpetology), Dr I.R. Swingland (chairman of the Ecology Research Group at the University of Kent at Canterbury), is also based in the UK. The IUCN SSC Group, amongst other interests, is involved with the conservation of Mediterranean tortoises (initiated by Lambert, 1984) which in southern Europe is being coordinated by David Stubbs, under Ian Swingland's direction.

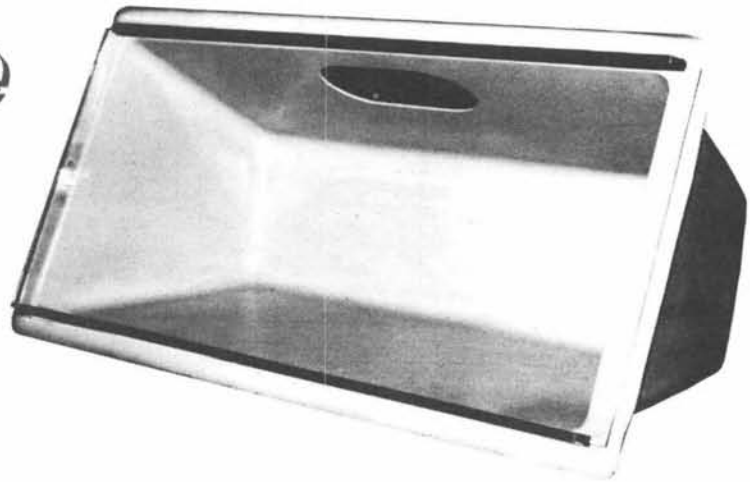
René Honegger, a vice-chairman of IUCN/SSC, is based in Switzerland (Zürich). He is well known in European conservation circles and has a long established involvement with the conservation of herpetofauna (e.g. Honegger 1968).

With BHS Conservation Committee, FFPS and SEH Conservation Committee acting in a concerted way, the conservation of amphibians and reptiles and their habitats in Europe is thus approached from a broad front (Lambert 1986), together with the initiatives of other voluntary organizations such as RANA (Group for the Protection and Study of **R**eptiles and **A**mphibians in **Na**ture) — with branches in Belgium and Italy (D. Ballasina, *in litt.*; Langton 1987b) — e.g. Project CARAPAX, and SOPTOM (Station d'Observation et de Protection des Tortues des Maures) in southern France (e.g. Devaux, Pouvreau, Stubbs and members of SOPTOM, 1986; Langton 1986c). There are in addition many other, often more local, voluntary and national bodies involved with wildlife protection generally which include species of herpetofauna and their habitats.

The problem of frog collection, especially in France, in relation to the well-known French culinary delicacy of frog-legs has been considered by Dubois (1983). Drs A. Dubois and J.-J. Morère, based in Paris, co-founded the Société Batrachologique de France (Société pour l'Etude et la Protection des Amphibiens) with conservation as a major aim (Morère 1982). A Europe-aimed frog-leg trade, from India, Bangladesh and Indonesia, has also developed and FFPS in the UK has taken an interest in this (Langton 1986b; Honegger 1981, 1984). The Royal Society for the Prevention of Cruelty to Animals (RSPCA), Horsham, has called for an indefinite ban on welfare grounds and the World Society for the Protection of Animals (WSPA), London, is also campaigning strongly against the trade because there are in addition links with pesticide problems and the association of collecting with human diseases in the tropical developing countries involved (Langton 1986d).

A report on herpetological activities in Europe 1983, which included much on conservation, was given earlier in *Herpetological Review* (Lambert 1985). The European Year of the Environment (21 March 1987 to 20 March 1988) has recently ended and it seems opportune that further information should be provided in this same publication on some of the herpetofaunal conservation work that is continuing to be carried out in Europe by NGO members associated with IUCN. Hopefully, this will keep members of SSAR and other herpetologists based in North America and elsewhere appraised of developments. It is important that such publicity should engender a wider appreciation of what so far has been achieved for it is a pertinent point that neither amphibians nor reptiles were considered at two recent significant meetings on a conservation/environmental theme in the UK. One meeting was the Bicentenary Joint Meeting of the Linnean Society of London and Royal Society for Nature Conservation (at the start of its 75th Anniversary Celebration), held in London on 19 March 1987 (only two days before the start of the European Year of the Environment). The other meeting was the British Crop Protection Council Symposium on Field Methods for the Study of Environmental Effects of Pesticides held in Cambridge, 28-30 March 1988 (only eight days after the European Year of the Environment).

Like SSAR in the USA, the BHS and SEH have Conservation Committees; FFPS, a conservation organization by definition, has employed a staff herpetologist. Since 1986, through the aegis of its Conservation Committee, the BHS has also employed a Conservation Officer to work alongside the Conservation Committee. He is also the Chairman of SEH's Conservation Committee. The FFPS staff herpetologist is secretary both of the SEH Conservation Committee and of a joint FFPS/SEH UK Herpetofauna Working Group. Rene Honegger and Brian Groombridge are also members of the SEH Conservation Committee. Amongst other functions, the FFPS staff herpetologist edits *Herpetofauna News,* which is published by FFPS (a member of IUCN since its inception) and circulated to FFPS members upon request and also with publications of UK-based ASRA (Association for the Study of Reptiles and Amphibians), the Asociacion Herpetologica Espanola and SEH. Within the context of the main society, the BHS conservation officer's main terms of reference are:



- preparation of site dossiers with the UK Government's statutory body, the Nature Conservancy Council (NCC), for the National Key-Sites of sand lizards (*Lacerta agilis*), smooth snakes (*Coronella austriaca*) and natterjacks (*Bufo calamita*), all of which are rare species in Britain, and to advise on habitat management needs where these are still lacking
- coordination of the BHS monitoring programme for these species, site protection, rescues from doomed sites, captive breeding and subsequent release
- organization of field surveys and restoration management of breeding sites of the great crested newt (*Triturus cristatus*), another rare species, involving liaison with a project funded by NCC, at Leicester Polytechnic.

Quite early on in the movement to conserve herpetofauna in Europe (although 66 years after FFPS was founded) and more particularly in the UK, the BHS Conservation Committee was founded in 1969. Its aim is to promote the conservation of all twelve native amphibians and reptiles in Britain, especially (as a priority) the four most endangered forms. Because amphibians and reptiles have very limited powers of movement and dispersal, they are particularly vulnerable to rapid changes in their habitats. Unlike other groups (e.g. seed plants, insects and even birds), they do not readily recolonise habitats over great distances. Even quite temporary disruption of an area can lead to irreversible loss of species (BHS Conservation Committee 1970). Amphibians and reptiles are also valuable indicators of the health of natural environments (Lambert 1987) and it has now become established that the Amphibia and Reptilia include the highest proportion of endangered species of any of the vertebrate groups. The BHS became an NGO member of IUCN in 1980 (SEH joined in 1984).

In Britain, it was clear by the late 1960s that many of the species of amphibians and reptiles were in marked decline. In addition, because of the widespread fear of snakes, the persecution of the adder (*Vipera berus*), Britain's only venomous species, was coupled with the destruction of creatures bearing any resemblance to it. These included two harmless snakes, the grass snake (*Natrix natrix*) and the rare and endangered smooth snake, and also the slow worm (*Anguis fragilis*), a legless lizard.

In consultation with the NCC, research into the detailed distribution initially of the natterjack, sand lizard and smooth snake indicated that these three species were more or less confined to two habitat types: lowland dry heath and coastal sand dunes. The loss of lowland heath, itself an endangered habitat, in southern England has been caused by vast afforestation programmes, agricultural reclamation, mineral extraction, building development and a number of (man-made) fires. This has resulted in an enormous decrease in the populations of the sand lizard and the smooth snake, while the natterjack is now virtually extinct on heathland for the same basic reasons, and also because so few non-acid breeding ponds remain. Conversely, natterjacks in their stronghold in NW England breed successfully in the slacks of coastal sand dunes, whose well vegetated frontal ridges and fixed dune habitats still support a few small remnant outrider populations of sand lizards. The coastal sand dunes in NW England have survived better than lowland dry heaths, but the despoliations of the holiday industry (holiday camps, trippers' motorcars) have taken their toll. Dune slacks tend to dry up more often than in former times, partly due to local drainage 'improvements' for building and human recreational (golf course) purposes, causing breeding failure (see also Tamarind 1975).

Reptile Cages

FOR THE AMATEUR
OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door is inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $33.95
24" Wide, 12-1/4" High, 12-1/2" Deep
250 sq. in. Floor Area, Single Vent

36" Reptile Cage $58.95
36" Wide, 18" High, 19" Deep
580 sq. in. Floor Area, Double Vent

Prices include freight charges and are shipped via UPS. Institutions, zoos and dealers are invited to write on letterhead for quantity prices.

Habitat management to improve the prospects of the three rare species in Britain has been carried out by BHS members and other volunteers. Heathland has been restored by brashing and the removal of encroaching birch and self-sown pine trees, and the herbicidal treatment with asulam of bracken (a fern, *Pteridium aquilinum*), often growing in the wake of fires and with which heathers (*Erica* spp. and *Calluna vulgaris*) are unable to compete. Small sand patches have been created, often by using rotivators, for egg-laying by sand lizards. On coastal dunes and inland heaths, ponds have been excavated using mechanical scrapers. Increases as a result of breeding have occurred in sand lizard (Corbett & Tamarind 1979) and probably smooth snake populations. Other heathland rarities like the Dartford warbler and nightjar, spiders and many other invertebrates have also increased.

With the agreement of NCC, BHS Conservation Committee members breed sand lizards in captivity and release progeny on suitable protected and managed heathland and dune sites. Due attention is paid to separation of genetically different races by means of an agreed translocation policy, to which argument the BHS Conservation Committee (1984) has contributed. A programme for the reintroduction of natterjacks to a series of heathland sites has also begun. Pond construction has enabled thousands of young natterjacks to metamorphose and successfully leave the water each year.

The success of this work has depended on funding and liaison with many other organizations, including WWF (UK), NCC, Vincent Wildlife Trust Fund, H.J. Heinz Ltd. and the Carnegie (UK) Trust Fund. Assistance has also been received from the British Petroleum Company plc. The full-time conservation officer of the BHS was employed as a result of grant aid to extend and consolidate the protection of the endangered British herpetofauna and their habitats.

With the passing of the UK's 1981 Wildlife and Countryside Act, partly ratifying the 1979 Berne Convention on the Conservation of European Wildlife and Natural Habitats, the great crested newt also became listed as a rare and endangered species. NCC are seeking information on this species and have appointed national survey coordinators on its distribution and status in Britain, especially since many ponds have become infilled, polluted or overgrown. In line with the much publicized 1983 European Year of the Water's Edge, a campaign was begun to manage and restore ponds for the continued survival of the great crested newt in Britain. Of the commoner species, there has been the widely publicized Toads-on-Roads Campaign (e.g. Clines 1987; Young 1988) following the precedent set in continental Europe. In 1984, over 20,000 toads (*Bufo bufo*) were rescued at reported sites; the figure for 1985 was 50,000, with many hundreds of people taking part. By 1987, over 100,000 toads were rescued at over 300 officially recognized toad migration routes.

In 1985, FFPS started a specifically herpetological programme; and, following a working group set up in the 1970s, the conservation of Britain's herpetofauna and their habitats received a further input when the UK Herpetofauna Working Group was established, under the aegis of FFPS (Langton, 1985a). The Group is affiliated (Langton 1985c) with the 1979-founded SEH, which became an IUCN NGO member in 1984. The reasoning behind the affiliation was:

A. to help raise funds for conservation projects of high priority in mainland Europe, especially involving expatriate British and nationals of other European countries, and also to increase SEH membership in the UK;

b. to select the UK for the formation of a semi-national group of this kind in recog-

nition of the influence that such statutory UK bodies as the NCC and the Department of the Environment (DoE) have in official European conservation circles.

Organised by the staff herpetologist as part of FFPS's herpetofauna programme, which has a major educational and advisory function in the UK, the Working Group's objectives are to help coordinate herpetofauna conservation in Europe and overseas, and to liaise extensively with government and non-government representatives over policy and new initiatives. Five areas were identified as requiring special attention:

1. integrating the UK with the rest of Europe in terms of conservation policy and practice, and investigating the functioning of the European Community (EC), particularly in relation to nature conservation;
2. co-ordinating objectives for conserving amphibia and reptiles in the UK;
3. co-ordinating objectives for monitoring and influencing policies in matters relating to national and international trade in herpetofauna;
4. acting as a focus for liaison with NCC on important, especially international, issues and policies; and
5. assisting with the dissemination of ideas on conservation matters and the conclusions of the Working Group through such outlets as *Herpetofauna News*.

FFPS have instigated several projects and activities in the UK. These include:

- Toads-on-Roads (*Bufo bufo*) Campaign (Langton 1985b, 1985d, 1986a, 1987a). The installation of the first toad tunnel in the UK, opened by the Lord Skelmersdale in March 1987 (Clines 1987);
- Snakes Campaign, to establish the true incidence and effects of adder bites (leading to an education programme to counteract the unnecessary fear instilled in the general public). The use by grass snakes of various egg-laying substrates has been investigated;
- Pet shop enquiry (some sell native British and exotic species illegally, without a proper license from the UK Government's DoE) (Langton, 1986e); and
- County recording of amphibians and reptiles. The Annual Herpetofauna Recorders' Seminars instigated by FFPS in conjunction with the Biological Records Centre (e.g. Arnold 1986); 150 people attended in 1987.

The Zoological Society of London has undertaken several new herpetological projects (Langton 1986f), some in conjunction with FFPS. These are designed to complement the educational value of the collection in London Zoo's Reptile House and to improve public awareness and understanding of reptiles and amphibians. An exhibition on many aspects of snake venom was prepared, and a smaller exhibition shows examples of reptile skins and other products controlled by such international regulations as CITES (the Washington Convention 1973); another exhibit discourages the casual keeping of exotic species by the general public.

Britain and Ireland are offshore islands of NW Europe. The hard experience, not least the political experience, gained by BHS Conservation Committee members in conserving the rare herpetofauna in Britain is being complemented with initiatives for similar work in some parts of the continental mainland of Europe (Corbett 1981). One of the founding members of the BHS Conservation Committee has become Chairman of the 1981-founded Conservation Committee of SEH. Through the aegis of this Society (Corbett and Podloucky 1982), field investigations and conservation assessments have been initiated on the status of the rarest species of European amphibians and reptiles as the result of successfully presenting a strategy for the establishment of 'biogenetic reserves' (Corbettt 1986) to the Council of Europe (CoE) in Strasbourg.

In following the work of Honegger (1978) and the precedent set by the inclusion of all species of herpetofauna on the Appendices of the Berne Convention, CoE have recognised the particular vulnerability of the amphibians and reptiles. A priority rating has been given to all species in CoE countries based on the detailed results of a Europe-wide conservation mapping exercise carried out beforehand, combined with a review of available literature and existing field records. Species were given categories of rarity from 1-10, and most of 1 and some of 2 were selected. The work was funded by CoE and IUCN, with contributions from WWF (UK and Netherlands). Recommendations for biogenetic reserves were based on:

1. a selection of priority species for which sufficient information allowed meaningful reporting;
2. the identification of potential sites within particular areas resulting from field assessments carried out by SEH Conservation Committee members; and
3. a definition of key areas which contained an assemblage of herpetofaunal species, notably those of rarity categories 2, 3 and 4.

The **species** that have been covered by the recommendations are: *Proteus anguinus, Alytes muletensis, Bombina bombina, Pelobates (fuscus) insubricus, Rana latastei, Podarcis lilfordi/pityusensis* island complexes, *P. milesensis, P. hispanica atrata, Gallotia (aff.) simonyi, Vipera (ursinii) rakosiensis, V. (ursinii) ursinii, V. lebetina schweizeri* and the marine turtles, *Caretta caretta* and *Chelonia mydas*.

The **key areas** that have been identified which contain assemblages of species of high rarity category have so far been NE Greece and SE Sardinia (Italy). It is hoped that further areas will also be included. Interestingly, the selected sites and areas for certain species overlapped with those of other fauna and flora, e.g. the riverine forests of the Po Valley (Italy) and the endemic flora of the Balearic islands. The overlap also includes such species as the black vulture (*Coragyps atratus*), the osprey (*Pandion haliaetus*) and the monk seal (*Monachus monachus*).

The Council of Europe has recognised the problems facing the European herpetofauna and applied funding for the Biogenetic Reserve initiative. Hopefully, their action in funding such conservation work will set a precedent and be followed by the Commission of the European Communities in Brussels. There is a strong possibility that the SEH Conservation Committee will become IUCH's first regional SSC group, namely the European Herpetofaunal Group, and the Committee is already engaged in preparing an Action Plan.

ACKNOWLEDGMENTS

For kindly commenting on an earlier draft of this article, we would like to thank the following former Chairmen of the BHS Conservation Committee: Dr Trevor Beebee (1977-82) and Prof. G.A.D. Haslewood (1983-87). Mr John Burton (Executive Secretary until 1988 of FFPS) also commented on the manuscript.

NOMENCLATURAL NOTES ON REPTILES OF THE UNITED STATES

We have discovered a number of nomenclatural anomalies that were perpetuated in "Standard Common and Current Scientific Names for North American Amphibians and Reptiles" (Collins et al. 1982). The corrections to scientific names presented here are required under the provisions of the third edition of the "International Code of Zoological Nomenclature" (1985).

The most common nomenclatural error involves the failure of an adjectival species-group name to agree in gender with the generic name as required under Articles 31(b) and 32(d) of the Code. These changes are:

1. *Elgaria panamintinus. Elgaria* (etymology unknown) is a feminine generic name that requires *panamintinus* (NL: belonging to the Panamint Mountains) to change from the masculine to the feminine form. The proper combination is *Elgaria panamintina.*

2. *Gambelia silus, G. wislizenii maculosus,* and *G. w. punctatus. Gambelia* (NL: commemorating W. Gambel) is a feminine generic name that requires *silus* (L: pug-nosed), *maculosus* (L: spotted), and *punctatus* (L: dotted) to change to feminine forms. The correct combinations are *Gambelia sila, G. wislizenii maculosa,* and *G. w. punctata.*

3. *Gyalopion quadrangularis. Gyalopion* (Gr: small hollow) is neuter; *quadrangularis* (L: having dorsal quadrangular blotches) must change to the neuter form. *Gyalopion quadrangulare* is the proper formation.

4. *Lampropeltis getulus* and *L. g. niger. Lampropeltis* (Gr: shiny shield) is a feminine generic name and requires the masculine adjective species-group names *getulus* (L: Getulian) and *niger* (L: black) to change to the feminine form. Although the change from *niger* to *nigra* is clear, the change from *getulus* to *getula* is less so. One could argue, under Article 31 (b) of the Code, that *getulus* should be considered a noun (L: a resident of Getulians). This position is analogous, however, to noting that "Kansan" could be used as a noun in the phrase "the Kansan," then using this as justification for saying it should be considered a noun in the phrase "the Kansan Glossy Snake." We do not accept this interpretation and regard *getulus* to be an adjective. The correct combinations are *Lampropeltis getula* and *L. g. nigra.*

Cope (1860) was the first to use *Lampropeltis* in combination with species names and was consistent in his treatment of the genus and species as feminine. However, subsequent authors (including Cope) have been remarkably inconsistent, frequently treating *Lampropeltis* as both masculine and feminine within one publication.

5. *Thamnophis sirtalis pallidula. Thamnophis* (Gr: bush snake) is a masculine genus that requires *pallidula* (L: somewhat pale) to change from the feminine to the masculine form. The correct combination is *Thamnophis sirtalis pallidulus.*

According to Articles 11(h)i of the 1985 Code [as well as Article 11(g)i of the 1961 Code], a Latin species-group name must be, or be treated as, an adjective or a noun. If necessary, names should be changed to conform with correct terminations as specified by Articles 31(c) and 32(d)ii. One example of this error was retained in the Common and Scientific Names checklist:

1. *Micrurus fulvius tenere. Tenere* (L: delicately) is an adverb and must be modified to the masculine adjectival form, *tener,* to agree with *Micrurus* (L: small tail). The correct combination, first made by Cope (1875), but ignored subsequently, is *Micrurus fulvius tener.*

Occasionally, authors have misinterpreted nouns to be adjectives. Nouns used as species-group names do not modify their spellings with changes in gender of generic names associated with them [Article 31(b)ii]. Two cases of this error were perpetuated in the checklist:

1. *Hypsiglena torquata ochrorhyncha.* As originally named by Cope (1860), the combination was *Hypsiglena ochrorhynchus.* It is clear that Cope intended *ochrorhynchus* (Gr: yellow nose) as a noun used in association with the feminine generic name *Hypsiglena* (Gr: high eye). Thus, the treatment of *ochrorhynchus* as an adjective is incorrect. The correct combination is *Hypsiglena torquata ochrorhynchus.*

2. *Nerodia rhombifera.* As originally formed by Hallowell (1852), the combination was *Tropidonotus rhombifer. Rhombifer* (NL: rhomb bearer or rhomb bearing) either can be considered a masculine adjective or a noun. In cases such as this, Article 31(b)i specifies that the species-group name must be considered as a noun. Regardless of its current placement in a genus with feminine gender, *rhombifer* does not change its spelling. The correct combination is *Nerodia rhombifer* (first used by Johnson 1987), an arrangement analogous to that in the combination *Pseudacris crucifer.*

In another case an unjustified emendation was retained in the checklist. [Note: the unjustified emendation of *platirhinos* in *Heterodon platirhinos* to *platyrhinos* has already been noted by Platt (1985)].

1. *Lampropeltis triangulum multistrata.* In the original description (Kennicott 1861) the name was formed as *Lampropeltis multistriata.* Although this was subsequently emended to *multistrata* (Cope 1861), this emendation was unjustified under the provisions of Art. 33. The correct formation of the name is *Lampropeltis triangulum multistriata.*

In another case a species-group name had inexplicably been emended from a correct to an incorrect form, and perpetuated in the checklist:

1. *Trionyx spiniferus asperus.* Originally, *Asper* (L: rough) was correctly formed (*Aspidonectes asper* Agassiz 1857). Its subsequent

emendation to *asperus* was wrong. The correct combination is *Trionyx spiniferus asper*.

Because *Iguana* has been reported as introduced and breeding in the United States (Wilson and Porras 1983), it is appropriate to comment here on the spelling of the species name. Linnaeus (1758: 206) named the green iguana *Lacerta igvana*. It is clear from his usage elsewhere on the page (e.g., *vulgaris, aquatica*) and his notation of pre-Linnaean names (e.g., Yvana, Igvana, Leguan) that the use of a "v" rather than a "u" in *igvana* was not as romanized "u." The correct spelling (under Art. 33) of the species name is *igvana*. Laurenti (1768) erected the generic name *Iguana*, spelled with a "u." Therefore, the correct combination should be *Iguana igvana*, analogous to *Gekko gecko* or *Mabuya mabouya*. However, in light of the fact that no one, other than Linnaeus, has ever used *igvana* we are preparing a petition to the International Commission of Zoological Nomenclature for conservation of the spelling *iguana*.

NEW LOCALITY RECORDS IN ARGENTINA AND PARAGUAY FOR CHELID TURTLES, *Platemys pallidipectoris* (FREIBERG) AND *Platemys macrocephala* (RHODIN *ET AL.*)

A review of the chelonians deposited in the Museo Argentino de Ciencias Naturales Bernardino Rivadavia (MACN) in Buenos Aires revealed five heretofore unrecorded specimens of *Platemys pallidipectoris*, including two from a previously unrecorded province. Two specimens of *Platemys macrocephala* were also in the collection, representing the first specimens recorded from Paraguay. All specimens in question had been mislabelled *Platemys spixii* or *Hydromedusa tectifera;* the most recent identification of the MACN turtle collection had been accomplished by a visiting foreign herpetologist a few years prior to the author's visit in late 1985. No specimens of *P. spixii* were found in the collection.

PLATEMYS PALLIDIPECTORIS: Five previously unrecorded specimens of this rare chelid were examined at the MACN. Two of these, MACN 5.478 (shell only) and MACN 1.30483, an entire adult female, lacked data. The identification of the former specimen was assured by the presence of a bit of dried skin attached to the posterior carapace, on which the enlarged thigh tubercles were well preserved.

MACN 7.459 is an entire adult alcoholic specimen, collected by Marcos Freiberg around Resistencia, Chaco in 1940, and was included in the first series of Argentinian *spixii* (Freiberg 1940). This specimen bears a second tag with the number 2474 from the Museo de Entre Rios, where the other two specimens of the *spixii* series presumably remain. The presence of this animal at the MACN could not be explained by either the director of herpetology, Jorge Cranwell, nor by Dr. Freiberg (pers. comm.). The correct identity of this specimen as *pallidipectoris* had already been deduced from Freiberg's detailed description of this specimen in 1940 (Rhodin and Mittermeier 1984).

MACN 8626 is a complete male specimen, collected by Cranwell and Giai in 1945 at Estancia Las Guampitas, near Jobson, Depto. Vera, Santa Fé Province. According to the senior collector, this specimen was found in a pond (*estero*). This turtle extends the known range of *P. pallidipectoris* about 275 km to the south of the nearest recorded location, Resistencia, Chaco.

MACN 1.30482 was collected by Luis Guerrero in "northern Santa Fé Province," and was deposited in the MACN in 1980. This whole specimen is a female. The only other specimen of *P. pallidipectoris* in the MACN (housed separately) is the type, MACN 1731. In addition, an adult specimen of this turtle was collected near Castelli, Chaco and taken alive to the Buenos Aires Zoo in January 1985 according to Tomás Waller of the Fundación Vida Silvestre Argentina. On the author's visit to the Buenos Aires Zoo the turtle could not be located. Castelli lies ca. 60 km N-NW of the type locality, Roque Saenz-Peña, Chaco (Freiberg 1945).

PLATEMYS MACROCEPHALA: MACN 1.8287 and 1.8288 are the shells only of a juvenile and adult specimen from Estancia Palo Santo, Puerto Casado, Paraguay, collected by Cranwell in May 1946. He recorded having found these empty shells at the edge of a canebrake (*cañaveral*). The juvenile, with a carapace length of 93.1 mm, is the smallest recorded specimen of *P. macrocephala*. Some of the dorsal scutes are lacking on both shells, revealing the absence of neural bones. The juvenile's carapace readily exhibits the increased depth for which *P. macrocephala* is so distinct. The occurrence of *P. macrocephala* in the area of Puerto Casado, Paraguay reinforces the accuracy of the distribution map provided by Rhodin et al. (1984); Puerto Casado lies at the southernmost tip of the designated range. This record represents the first actual verification of the occurrence of *P. macrocephala* in Paraguay.

The author wishes to thank the following individuals for their assistance at the MACN: Jorge Cranwell, director of herpetology, and his colleagues Marcelo Canevari and Gustavo Carrizo. Dr. Anders Rhodin verified via photos the identity of the specimens photographed (four of the seven).

NOCTURNAL ACTIVITY IN THE BOLSON TORTOISE (*Gopherus flavomarginatus*)

While studying the basic biology of Bolson tortoises, *Gopherus flavomarginatus,* at the Mapimí Biosphere Reserve's Laboratorio del Desierto in Durango, México (26°38'N/103°46'W), one of us (MAR) suggested that tortoises may emerge from their burrows after dark in response to rising soil temperatures. To ascertain whether emergence occurred routinely after field observations ceased (±2000 h), we re-wired an analog travel alarm clock so that a long tripwire extended from one pole of its 'AA' battery, across the burrow mouth of an adult female tortoise (#95, 7.3 kg BW), to the other pole. The clock was set at ±2000 h for ten nights between 17 July and 09 August 1980 and read the following morning at ±0700 h. In addition, one of us (MAR) observed the animal from 2000 h until 2340 h on 30 July 1980.

Tortoise #95 emerged every one of the ten nights after or about 2000 h (range = 1942-2326 h). On the evening of continuous monitoring, #95 emerged, reentered and reemerged from its burrow, and rested on either the burrow slide or mound. During the three hours and forty minutes of observation her T_b declined from 33.2 to to 29.6°C, as determined from deep body radiotelemetry. We believe this behavior may be related to elevated ambient temperatures. Figure 1 plots the temperatures of i) air in the shade ii) soil in the shade and iii) soil at 15 cm depth for the periods 09 July to 04 August (dry season) and 05 August to 20 August (rainy season) during 1980. In the dry season, both shaded air and soil temperatures peak at 1600-1700 h and by 2000 h are ≤ 34°C; in the wet season they are ≤ 26°C by 2000 h.

Deep soil temperature, however, follows a different pattern. Solar energy is stored increasingly during the day and refluxes as infrared radiation at night, so that temperatures reach ≥ 37°C between 1700-2000 h in the dry season and ≥ 31°C during the same times in the rainy season. All dry versus rainy season microclimatic temperatures were statistically different (ANOVA, df=139,2326; F= 129.35; p≤ .01). Similarly, temperature measurements made at night of the soil at 6 cm and 15 cm depth in the Mohave desert during July (MAR, unpublished observations) showed that soil temperatures exceeded 34°C between 2300 and 0100 h.

During the 23 days of this study, tortoise #95 had a daily average body temperature (T_b) of 30.2 ± 0.9°C (N=1,662). The average T_b at the initiation of diurnal foraging was 29.6 ± 1.7°C (N=21). Perhaps tortoises are activated nocturnally by elevated ambient burrow and/or soil temperatures, but are prevented from leaving the immediate vicinity of the burrow by their sensory (visual?) limitations. Luckenbach (1982) suggested that the desert tortoise, *Gopherus agassizii,* may emerge nocturnally during rainstorms, however, he provided no data. Our observations at Mapimí suggest that *G. flavomarginatus* does emerge during nocturnal rains. In contrast, Voigt (1975) reported that "in 3 years of close observation of the desert tortoise, nocturnal or pre-dawn activity was never observed in the field.' Similarly, Rose and Judd (1982) reported that *G. berlandieri* is diurnal and Douglass and Layne (1978) never detected nocturnal activity in *G. polyphemus.* The Aldabran tortoise, *Geochelone gigantea,* a non-burrowing species, apparently rests on the ground surface at night (Swingland and Frazier 1979), but is not active except when nesting.

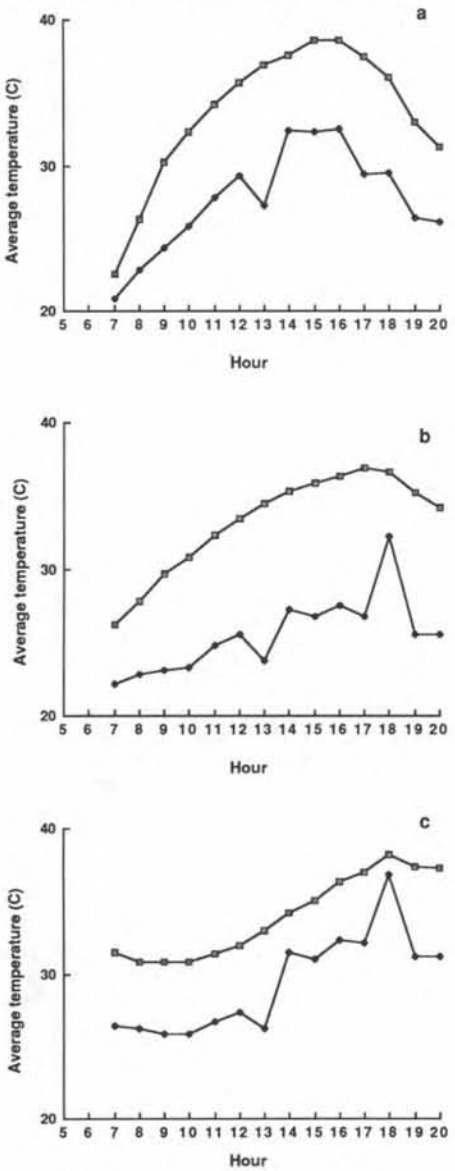

Figure 1. Average hourly temperature for dry season (upper curves) and wet season (lower curves) at Mapimí Biosphere Reserve during 1980. a= shaded air, b= shaded soil surface, c= soil at 15 cm depth.

Nocturnal activity by apparently diurnal iguanid lizards does occur. Mora (1986) reported nocturnal activity related to nesting in *Ctenosaura* and one of us (MAR) has radiotracked *Crotaphytus wislizenii* which were active and feeding at night during elevated temperatures in the Mohave Desert. We suspect that nocturnal emergence in diurnal reptiles occurs more widely, but has remained undocumented because most workers have not looked for it.

ORIGIN OF THE POPULATION OF *Rana aurora draytonii* ON SANTA CRUZ ISLAND, CALIFORNIA

Sweet and Leviton (1983) reported the natural occurrence of the California red-legged frog (*Rana aurora draytonii*) on Santa Cruz Island, Santa Barbara County, California, based on three specimens (CAS 45230-32) collected by Joseph Richard Slevin on 17 May 1919 from the vicinity of Pelican Bay. Previously, Storer (1933) reported this population to be the result of transplanted frogs from mainland California. However, his statement was complicated by also indicating that the Southern Pacific rattlesnake (*Crotalus viridis helleri*) was introduced on Santa Catalina Island, California. Since *C. v. helleri* has been known from Santa Catalina Island since 1876 (USNM 9959), the reliability of Storer's comments was questioned.

Recently, I had the opportunity to examine Tracy Irwin Storer's field notes and personal files (housed at the California Academy of Sciences). Inspection of his file on "alien reptiles, amphibians, [and] fish [in] Calif[ornia]" revealed that Slevin informed Storer in September 1931 that *R. a. draytonii* had been introduced on Santa Cruz Island a short time prior to Slevin's 1919 collecting expedition. Additionally, Storer's notes revealed that reports by "old-timers" regarding the introduction of *C. v. helleri* on Santa Catalina Island, as cited by Bryant (1915), were erroneous and the subspecies was native to that locality.

Slevin (1928) probably omitted the Santa Cruz Island locality for *R. a. draytonii* because the frogs were an introduction. Slevin was notoriously lax at keeping detailed field notes and his field journals for the period (in a pocket diary marked "1917") provide no further details other than the collection of the specimens. According to testimony presented to Storer during meetings in Berkeley, California, from 19-23 July 1938, "frogs" were apparently also liberated on nearby Santa Barbara and San Miguel islands (Field Notebook #11, p. 2214b).

The origin of the *R. a. draytonii* stock on Santa Cruz Island remains unknown, but I speculate that it probably came from either Sigmund F. Beck and Company, San Francisco, or S.C. Coombes, South San Francisco, the two major frog dealers in the state between 1910 and 1920. The frogs were probably introduced by Basque or French workers on the island to provide a ready source of frog legs. Santa Cruz Island has had a working cattle and sheep ranch and an associated winery in Valle del Medio near Pelican Bay since the 1850s (Brumbaugh 1980).

My thanks to Drs. Ruth Risdon Storer and Milton D. Miller for providing access to T. I. Storer's field journals and to Johan C. Kooy for allowing me to browse through Storer's personal files. Jens V. Vindum assisted in examining J. R. Slevin's field journals.

RECOVERY FROM ICE-ENTOMBMENT IN GARTER SNAKES

Snakes typically select hibernacula that 1) permit descent below the frostline, 2) exclude light, and 3) provide protection from predators (Gregory 1982). Moisture availability is one environmental aspect of snake dens that has received little attention in the literature. Although both wet and dry dens may be used by the same species, there is evidence that the former provide superior overwintering conditions. For example, snakes occupying well-drained hibernacula may lose more mass due to the combined effects of dehydration and nutrient consumption than do those in moister sites (Maple and Orr 1968; Aleksiuk and Stewart 1971); this undoubtedly affects survivorship adversely. Conversely, hibernating garter snakes (*Thamnophis sirtalis*) voluntarily submerged in water at 4° C remained fully hydrated (74.4% of fresh body weight) over a 165 day period during winter (Costanzo 1985). No mortality occurred in this laboratory study.

It is not widely appreciated that several terrestrial snake species physically enounter and occupy standing water within dens during winter (Criddle 1937; Owens 1949; Carpenter 1953; Zaremba 1978; Sexton and Hunt 1980; Costanzo 1986). Additionally, at least *T. sirtalis* prefer to hibernate underwater (rather than in air) in laboratory hibernacula when given a choice (Costanzo 1985, pers. obs.). Although this behavior may be physiologically advantageous (e.g. thermal buffering, maintenance of body water content), potential hazards such as drowning or freezing undoubtedly exist. This report relates observations on the survival of garter snakes that accidentally became entombed in ice while hibernating underwater in the laboratory.

Eastern garter snakes (*Thamnophis s. sirtalis*) were collected as they approached a communal hibernaculum in Portage County, Wisconsin on 6 October 1985. Thirty-seven snakes were placed in a darkened laboratory hibernaculum and slowly exposed to declining temperatures (15 to 4° C over a 13 day period) in a Freas 815 low-temperature incubator. The snakes were contained in a box (99 X 53 X 42 cm) with a wooden frame and pegboard walls. The bottom of the box enclosed a thick-walled (4 cm) styrofoam container (27 X 39 X 32 cm) that was filled with ca. 27 l deionized water. Several rocks and twigs were placed in the container to facilitate vertical movements and to serve as anchors for submerged hibernating snakes. Structure was provided in the upper region of the box by loosely packing it with crumpled paper. Thermistor probes fixed in the air and water spaces permitted periodic determinations of hibernaculum temperature using a telethermometer (Yellow Springs Instrument Co., Model 44); 4° C ± 0.5° C was maintained after the initial exposure regime.

On 20 November, many voluntarily-submerged snakes were observed to be entombed in a large block of ice that had formed as a result of incubator failure. Air and ice temperatures in the hibernaculum at this time were 2 and 0° C, respectively. Although the exact time of ice formation is unknown, the system was observed to be operating normally when checked on 14 November. Judging from the mass of the ice that had formed, crystallization had probably begun at least three or four days prior to its discovery. Examination of the ice block (using a drill) indicated that the ice extended to the bottom of the box at the sides, but may have contained a small amount of water near the center.

Nine of the snakes were grouped in a corner of the container and were clearly visible under the surface of the ice. The completely encased bodies of these snakes were generally outstretched and made physical contact with one another. No portion of any snake protruded from the ice block; the nearest individual was about 3 cm below its surface. Twenty other snakes were also trapped within the container but could not be readily observed.

Eight snakes that escaped ice-entombment were tightly intertwined in an upper corner of the box. The body mass of this group ($\bar{X} \pm SE = 38.6 \pm 3.4$ g) was significantly ($P < 0.05$, $t = 3.45$) smaller than that of the group encased in ice ($\bar{X} \pm SE = 92.3 \pm 8.1$ g; $N = 29$). This difference is not easily explained; however, it may have been easier for smaller individuals to climb out of the container at the onset of ice formation.

The snakes were freed by allowing the ice to melt slowly at room temperature for 2.7 d. Freed snakes were immediately placed in an environmental chamber at 15° C (9:15, L:D) and observed over a period of several days.

Of the 29 snakes removed from the melting ice block, 18 (62.1%) survived. There was no difference in body mass between these snakes ($\bar{X} \pm SE = 90.8 \pm 11.0$ g) and those that died ($\bar{X} \pm SE = 94.8 \pm 12.0$ g, N=11).

Most dead and dying animals had a localized greenish-yellow discoloration of the ventral scutes approximately half-way from the snout to the cloaca. Internal examination of several animals showed that the gall bladder was flattened (presumably ruptured) and that bile had produced the staining. The distal portion of the liver and adjacent fat bodies were similarly discolored. Although this condition was a prominent feature of those snakes that succumbed, it is unlikely to have been the ultimate cause of death; several surviving snakes also showed a minor discoloration of ventral scutes. It is also unlikely that low temperature and tissue freezing were involved in the observed mortality since *T. sirtalis* from this population tolerates substantial freezing of their body fluids (Costanzo et al. 1988).

Anoxia may conceivably have contributed to the demise of some of the snakes in this investigation. Gas diffusion in ice is greatly reduced, thus ice-encasement might effectively inhibit trans-integumentary (as well as pulmonary) exchange. Also, the pressure produced by crystal formation and the resulting expansion of the medium might have injured some snakes. It is not known at present how some of the animals were able to endure this combination of adverse conditions whereas others were not. It is clear, however, that the observed differential survivorship was independent of body size.

The use of abandoned farm wells as hibernacula is common for several snake species (*T. sirtalis, Elaphe vulpina, Storeria occipitomaculata*) in central Wisconsin (Costanzo 1986). Since these dens become partially filled with rainwater during autumn, it is probably not unusual for the inhabitants to encounter ice formation during the severe winter weather characteristic of this region. The probability of occurrence of this potentially lethal situation in dens should increase with frost depth (inversely related to snow cover), low ambient temperature, and decreasing den depth.

ACKNOWLEDGMENTS

I thank Dirk Vevea for aiding in the collection of animals. Dr. Dennis Claussen and anonymous reviewers made helpful comments on the manuscript.

REPRODUCTION IN CAPTIVE LOUISIANA PINE SNAKES, *Pituophis melanoleucus ruthveni*

Since its description 58 years ago (Stull 1929), the Louisiana pine snake, *Pituophis melanoleucus ruthveni* has remained a herpetological obscurity. Most literature accounts have been based on chance collections of single specimens (Clark 1949; Smith and Kennedy 1951; Mitchell and Tinkle 1960; Walker 1965; Tennant 1985). Thomas et al. (1976) found only 39 specimens extant in collections. *Pituophis m. ruthveni* occurs in western Louisiana and a small portion of adjacent Texas (Thomas et al. 1976), in an area that was once a disjunct portion of the pine forest belt that dominated much of the southeastern U.S. (Lohoefener and Lohmeier 1981). The original habitat association of longleaf pine/blackjack oak scrub forest was destroyed by logging in the 1920s (Maxwell 1973; Crocker 1979). The rapid and total destruction of the habitat of *P. m. ruthveni* has probably contributed in making it the most endangered and poorly known large colubrid snake in the U.S. (Reichling 1986). The tenuous condition of natural populations of *P. m. ruthveni* make captive breeding of this form especially important. Aspects of its reproductive biology are unknown, and the only literature report concerning captive reproduction is a brief note by Henley (1985). In this paper, I report details of a successful captive breeding of *P. m. ruthveni*.

MATERIALS AND METHODS

A male *P. m. ruthveni* (137 cm SVL) was obtained on 18 February 1986 from a commercial dealer. The specimen had reportedly been collected near Leesville, Louisiana, six years earlier as a hatchling. A second male (121 cm SVL) and a female (137 cm SVL) were received on 19 November 1986. This second male was acquired on a breeding loan from the Louisiana Purchase Gardens and Zoo in Monroe, Louisiana, and had been collected at Lucky, Louisiana (P. Lindsey, pers. comm.). The female was taken near Ringgold, Louisiana.

The snakes were maintained separately in 114-liter aquaria. Beechwood shavings were used as a substrate, and provided a medium into which they could burrow. A photoperiod that ranged from 7L:17D in December to 17L:7D in June was provided using two 40 watt fluorescent tubes. Two 200 watt incandescent bulbs provided higher light intensity and greater diel temperature range from March through November ($\bar{X}$ daily range = 23°-32° C). The snakes were maintained at lower temperatures ($\bar{X}$ daily range = 11°-15° C) from December through February, during which time they became inactive and did not feed.

The snakes fed exclusively on small rats, refusing day-old chicks. I have relied on feeding chicks to other subspecies of *P. melanoleucus* as an effective way of maintaining high body mass in females (Reichling 1982). Seven-to-ten small rats (ca. 40 g each), offered at 5-6 day intervals, were necessary to achieve the body condition required for successful captive reproduction in this species.

Introductions were made from mid-March through early May. Initially, the female was simply alternated between males for 24 h periods, but no courtship was observed. Beginning in April males were introduced in an effort to induce combat behavior and elicit breeding responses.

Eggs were incubated in 11-liter plastic boxes, in coarse grade vermiculite moistened with water following the method of Tryon

Figure 1. Juvenile *Pituophis melanoleucus ruthveni*, showing clearly defined anterior blotching. Numbered increments = 1 cm.

(1975). The box was opened for a few seconds every week, and was provided with tiny holes drilled around the sides to allow additional gas exchange. Incubation temperatures fluctuated in a diel pattern ($\bar{X}$ daily range = 25°-31° C).

RESULTS AND DISCUSSION

Male-male introductions immediately provoked bouts of ritualized combat as described by Shaw (1951) for *P. m. melanoleucus*. After thirty minutes of combat behavior, the males were separated and the female placed with one of them. Courtship behavior was observed from both males throughout April, following this procedure.

Courtship behavior agreed in most aspects with that described for *P. m. melanoleucus* (Shaw 1951). It differed from other accounts of *Pituophis* courtship, and from my observations of the subspecies *melanoleucus, mugitus* and *lodingi*, in the character of the caudocephalic waves exhibited by the males. These waves were directed more ventrally, and did not involve movement of the body. They consisted of a rippling motion visible only in the ventral scutes, repeated in a rapid series of waves flowing posteriorly. They occurred while the male's body was laid loosely over the female, with no neck biting, and while the snakes were otherwise motionless. The last observed courtship was on 5 May 1987, when the female appeared gravid. No copulations were observed.

Pre-parturition ecdysis took place on 20 May. Four very large eggs were laid during the afternoon of 26 May, in a nest box filled with damp sphagnum moss. Three shiny eggs (3 x 11.5 cm, 3 x 12.5 cm and 3.5 x 10 cm) with translucent shells did not develop. A fourth egg (4 x 11 cm) was white, with a dry, leathery shell covered with calcium crystals, and appeared fertile. The fourth egg hatched on 25 July after a 60 day incubation period, calculated using the method of Gutzke et al. (1984).

The single male hatchling was extraordinarily large (55 cm TL). It resembled the adults in most aspects of color and pattern, but differed in several respects (Fig. 1). The entire ground color had a bright orange wash, created by thin streaks of pigment forming a median longitudinal line across each unpatterned dorsal scale. The anterior pattern lacked the heavy suffusion of dark pigment that obscured the nuchal blotches in adults, leaving the anterior blotches distinct and definable as in *P. m. sayi*. The bold, black ventral blotching characteristic of *P. m. ruthveni* was paler in the neonate, with many ventral blotches being a cloudy pink color.

I am aware of three additional clutches of *P. m. ruthveni*. The female in my study laid two infertile ova in 1986, and two clutches of five and four eggs have been produced at the Ellen Trout Zoo in Lufkin, Texas (G. Henley, pers. comm.). Based on all available data, it appears that *P. m. ruthveni* lays the smallest clutches, but the largest eggs (in both an absolute and proportionate sense), of any large U.S. colubrid snake. Although all Gulf Coast *Pituophis* have been shown to produce relatively small clutches of large eggs (Reichling 1986), *P. m. ruthveni* appears to represent the extreme of this reproductive mode in a geographic cline of decreasing clutch size and increasing egg size from north to south and west along the eastern U.S. coast. The subspecies *melanoleucus* lays the largest clutches and smallest eggs (7-24 eggs; length 4.8-6.4 cm; width 2.6-4.5 cm) among eastern U.S. *Pituophis* (Wright and Wright 1957), with *mugitus* and *lodingi* (7-9 eggs; length 9.0-10.5 cm; width 2.7-3.5 cm) following a trend toward smaller clutches and larger eggs (pers. obsv.). This reproductive character reaches its extreme in *P. m. ruthveni. P. m. sayi* has been proposed to be a member of an eastern complex of *Pituophis* based on similar snout morphology of subspecies examined (*melanoleucus, mugitus, sayi*) (Knight 1986), yet *P. m. sayi* diverges from the other members of this grouping particularly the neighboring subspecies *ruthveni*, by laying large clutches of small eggs (5-22 eggs; length 4.2-5.7 cm; width 2.8-4.2 cm) (Wright and Wright 1957; Fitch 1970), and more closely resembles the western group (*affinis* and *deserticola;* 4-24 eggs; length 4.0-5.0 cm; width 2.5-3.5 cm) in this respect (Wright and Wright 1957; Fitch 1970).

It is hoped that a captive breeding program can be established for this form, and that additional founders can be added to the group to better measure its reproductive potential. Until data can be presented showing that *P. m. ruthveni* populations are stable, the subspecies should be considered endangered and captive breeding should be an immediate priority.

ACKNOWLEDGMENTS

I thank the Louisiana Department of Wildlife and Fisheries for allowing me to conduct field work in Louisiana, Alan P. Jaslow and Raymond D. Semlitsch for reviewing early drafts of the manuscript, and my wife Ann for her assistance in the field and with captive husbandry of specimens. I am particularly grateful to Peter Lindsey and the Louisiana Purchase Gardens and Zoo for the loan of their male *P. m. ruthveni.*

TECHNIQUES

A SIMPLE METHOD TO MARK HATCHLING TURTLES

It is important to identify individuals reliably in long-term studies of growth, mortality, and reproduction. Here, we describe a method of tagging hatchling turtles in which wire rings are placed in the posterior marginal scutes. This method is inexpensive, easy to apply, can be used to identify a large number of turtles individually, and produces a tag that is retained over a long period.

The only materials required are a pair of needle-nosed pliers, wire cutters, and 35-lb steel trolling wire. Each tag consists of one or more 5-cm pieces of wire, each of which is passed through a posterior marginal scute

and bent to form a ring. By attaching each wire ring according to the scute numbering system of Cagle (1939), up to 1554 hatchlings can be identified individually. Color-coded plastic beads (e.g. Barriecraft Sales, 123 Dunlop Street East, Barrie, Ontario, Canada, L4M 1A6) can be added to the wire rings to increase the number of potential tags or to facilitate identification.

To attach the wire, one end of each 5-cm piece is sharpened by cutting it at a 45° angle. The sharpened end is pushed through the desired scute from the ventral side, close to, but not through, the skin (Fig. 1a). The ends are bent so that they overlap and the wire forms a double ring (Fig. 1b). The ring is tightened by drawing the ends anteriorly, leaving a small space for growth (Fig. 1c). The free ends are then cut and the ring adjusted so that no sharp points are protruding (Fig. 1d). The finished ring is approximately 3 mm in diameter. Although the rings could be made more secure by twisting or soldering the ends, this takes considerable time and would provide no significant improvement in retention of the rings because loss of rings is almost always by tearing through the scute (see below).

In the summer of 1985, 33 snapping turtles 1-2 years old were captured in the field, tagged with this method, and released. In October 1985, 281 hatchlings were tagged within 30 days of hatching. Of these, 130 hatchlings were tagged with wire only, and 151 others had colored beads strung onto the wire. The turtles were maintained in the laboratory until May 1986, when they were released into the wild.

In the eight months that these hatchlings spent in the laboratory, one of the 130 wire tags and nine of the 151 beaded tags were lost. Wires were ignored by the turtles, but some turtles snapped at the beads of others, especially pale-colored beads. No hatchlings suffered infection or damage from the rings, although on two occasions, two turtles locked rings.

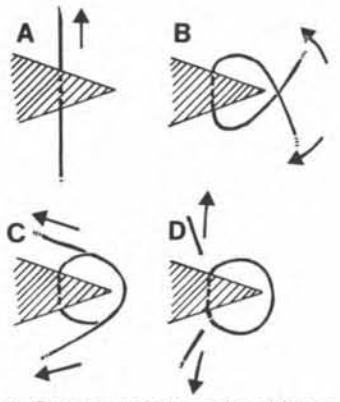

Figure 1. Steps in tagging a hatchling turtle with wire rings. Shaded area represents a section through a marginal scute of a hatchling. Anterior is to the left. A) A 5-cm piece of wire is sharpened and passed through the posterior marginal scute. B) Ends of the wire are bent over and under the carapace to form a ring. C) The double ring is tightened by pulling the ends anteriorly. D) The free ends are trimmed, and the remaining wire ring, about 3 mm in diameter, is tightened with pliers.

Of the 33 turtles tagged in the field in 1985, 10 were recaptured at least once that summer. Four were recaptured in 1986, three in 1987 and three in 1988. All retained the rings except two of the 1988 captures. These two animals had grown to over 100 g and could be notched. Of 22 unmarked hatchlings captured in 1986-1988, none had torn scutes that would indicate they had lost a tag.

The 130 turtles with wires only were weighed once a month and loose tags were adjusted when necessary. Therefore, tag losses in wild turtles may be higher than our observations on captives indicate. Conversely, the high density of hatchlings in our aquariums and their aggressive behavior during feeding may have made the loss rate higher for the beaded turtles than would occur in the wild. In the summer of 1986, we recovered 13 of the 281 turtles released in May 1986, and none of these had lost a tag. Therefore, it appears that these tags are reliably retained for two years in the hatchlings, and begin to be lost as the turtles reach a size at which they can be notched. The occasional loss of a ring in these first two years occurs when they are ripped out and this is readily detected. Loss after two years occurs because growth separates the tag ends. Initially this loss is revealed by the hole in the scute. Tags should be replaced by notches when turtles are large enough.

There are several other tagging techniques for small turtles now available (e.g. Miller 1955; Pough 1970; Schwartz 1981; Galbraith and Brooks 1984), and each has some advantages and disadvantages. Advantages of the technique we describe here are: the length of time the tags are retained; the speed with which tags can be applied; and the availability and low cost of the required materials.

USE OF SUBCAUDAL SCALE ANOMALIES AS AN AID IN RECOGNIZING INDIVIDUAL SNAKES

Mark-recapture studies on snakes usually rely on scale-clipping for identification of individual animals (Brown and Parker 1976), although other techniques such as photography of colour patterns have also been used (Ferner 1979; Fitch 1987). Scales regenerate over time, so that long-term recaptures may be difficult to identify. Recent studies on Australian common blacksnakes (*Pseudechis porphyriacus,* Elapidae) and water pythons (*Liasis fuscus,* Boidae) revealed that the number and position of divided *vs* entire subcaudal scales varied among individuals, and hence offered a means of recognizing individual animals. In addition to clipping ventral scales, we now routinely record subcaudal formulae, from the anal plate posteriorly, counting on the snake's right-hand side. The degree of detail recorded depends on the extent of variability among specimens in the scale characters counted. If simple counts of entire and divided subcaudals are insufficient to uniquely identify specimens, one can record (i) positions of aberrant subcaudals divided into three rather than two segments; (ii) partly divided ("creased") subcaudals, where the division into two separate scales is incomplete; and (iii) anomalies between counts on the right- and left-hand sides of the tail.

The subcaudal count usually can be summarized in a short formula. For example, a snake with the first subcaudal entire, second divided, third partly divided, fourth and fifth entire, and remainder divided, would be scored as "1E, 1D, 1PD, 2E,∞D." Alternatively, scale anomalies can be added to predrawn diagrams on data sheets. In our experience with mark-recapture studies, many such formulae are unique to particular individuals within a population. Among 53 *P. porphyriacus* from Bubalahla Creek via Taralga, New South Wales (including one litter of 10), 41 (77%) had unique subcaudal formulae. One formula (5E,∞D) occurred in four snakes, and four other formulae in two snakes each. In combination with data on sex, body size, geographic location and ventral scaleclips, these subcaudal formulae enabled us to easily recognise recaptured snakes. There were no duplications in subcaudal counts among the ten neonates from the same litter. Similarly, data on 115 *L. fuscus* from Fogg Dam via Darwin, Northern Territory, showed that 56 (49%) had unique subcaudal formulae. A single pattern (∞D) was shown by 37 snakes (32%), another (3E,∞D) by 9 animals, and other duplications by five or fewer individuals. Three duplications (all∞D) were observed among a litter of six hatchling *L. fuscus.*

Routine recording of subcaudal formulae may prove to be useful in other mark-recapture studies of snakes, and in other situations (e.g. captive specimens in large collections) where individual recognition is required. It is particularly valuable for studies on small species or on neonatal snakes, where scale-clipping is difficult and potentially injurious to the animal. In such cases, recording subcaudal formulae may permit individual recognition with a reduced number of ventral scale-clips. When used in combination with ventral scale-clipping, subcaudal scale formulae may significantly improve the

investigator's ability to recognize specific animals on recapture.

A METHOD FOR MANUAL VENTILATION OF TRANQUILIZED TORTOISES

Many modern clinical and field techniques in herpetology require the administration of anesthetic or chemical immobilizing agents. When the subject is immobilized, care must be taken to prevent prolonged apnea. During 1981, Bolson tortoises, *Gopherus flavomarginatus*, at the Mapimí Biosphere Reserve Laboratorio del Desierto in Durango, México were restrained for blood sampling via jugular venipuncture, cloacal palpation for sex determination, and the administration of oxytocin for induction of oviposition. Immobilization, accompanied by drooping of the upper eyelid (ptosis), and hind limb rigidity, resulted within 3-5 minutes after intramuscular injection of succinylcholine hydrochloride (0.50 mg/kg BW), a neuromuscular blocking agent. Body temperatures of tortoises examined ranged from 27-35° C.

During the course of these procedures, one of us (BB) developed a technique for maintaining adequate ventilation in immobilized tortoises without the need for tracheal intubation. The procedure consists of elevation and extension of the forelimbs while the subject is in a prone position, followed by direct rearward compression of the forelimbs alongside the head and into the axillary space (Figure 1). During this motion the humeri are kept parallel to the long axis of the body and the elbows are flexed at 90°. As a result, the lungs are filled as the pleuroperitoneum expands with the extension of the limbs, and emptied (through the nares) as compression occurs. The rigidity of the hind limbs augments this effect by preventing pressure relief through expansion of the abdominal cavity via the inguinal region. One to two complete cycles per minute are sufficient to perfuse adequately immobilized tortoises. We applied the technique continuously during the course of our examination (5-30 minutes) and once every 15 minutes for the next hour. In 6 years of experience since the technique was developed we have never experienced a fatality or complication in hundreds of uses involving more than 50 animals. The authors believe that the technique would be effective in all tortoises.

TECHNIQUES FOR PHOTOGRAPHIC SIZE ESTIMATIONS OF CROCODILIANS

Making accurate size estimates of subjects is often required during herpetological field work. Magnusson (1983) demonstrated that size estimations of crocodilians could not be made accurately by inexperienced observers from direct observation. Such difficulties are likely to be as acute, or worse, for other taxa.

Here I report on a generally applicable photographic method for improving the accuracy of size estimations. This method, developed during work on the black caiman *Melanosuchus niger* in Peru, allows direct calculation of the subject size from the image size in a photographic negative. Another method for photographic size estimations based on the same basic principle has been arrived at independently by Grahame Webb and coworkers for use with the estuarine crocodile *Crocodylus porosus* in the Northern Territory of Australia (Choquenot and Webb 1987). Both methods depend for their validity on the mathematical relationship between the variables in an image-producing (photographic) lens system. This relationship is expressed in Equation 1 below, which is derived from the lens formula

$$\text{(Equation 1)}\ H = \frac{U - F}{F} \times h$$

where: H = Subject size
U = Camera-to-subject distance
F = Focal length of lens
h = Image size in photographic negative

The convergence of the two methods perhaps emphasizes the practicality of what is essentially the same technique. The technique as developed for use with *M. niger* in Peru uses Equation 1 explicitly in its calculations, so I will call it the Lens Formula Method. Webb and colleagues' methodology depends on the basic truth of the formula, but does not use it directly. Rather their method employs an empirically derived calibration curve for each lens. I shall refer to it as the Calibration Curve Method.

LENS FORMULA METHOD

For the methodology developed with *M. niger* a series of photographs is taken perpendicular to the dimension to be measured. For each photograph the focal length of the lens used is noted together with the camera-to-subject distance. Camera-to-subject distance is read from an accurately calibrated real distance scale on the lens focusing ring. I found it necessary to recalibrate the distance scale etched by the lens manufacturer on the focusing ring for this purpose.

Given these values, and the size of the image in the resulting photographic negative, the actual size of the subject photographed can be calculated directly using Equation 1 above. Only sharply focused photographs should be used for this purpose, since poorly focused photographs indicate that the camera to subject distance read from the focusing ring was inaccurate. Special care must also be taken when measuring the image size in the photographic negative. As the multiplier in Equation 1, it can be an important source of error. Accurate measurement is not easy direct from the negatives, but it can be achieved by projecting the negative at a

standard magnification and calculating the original size of the image in the negative from the projected image. If only the head of the crocodile is photographed, the snout-vent length can still be estimated since the relationship between the two dimensions is well documented for a variety of crocodilians (e.g. Kramer and Medem 1955; Webb and Messel 1978; Montague 1984).

CALIBRATION CURVE METHOD

This method, developed by Webb and colleagues, involves taking a series of photographs of a standard metre rule at various distances recorded from an arbitary distance scale on the lens focusing ring. These data are used to scale the long axis of the photographic negative to real size at that distance. If for example the image of a one metre rule was X mm in a 2X-mm-long negative at a distance measured on the arbitary scale as Y, then the total length of the negative can be scaled to a real negative width of 2X metres at that distance. A series of such real negative widths plotted against their corresponding arbitary distances gives a calibration curve for the lens used. Thus, if during a survey a perpendicular photograph of a crocodile's head is taken at the distance Y, and the image occupies one quarter of the frame length, then its real length is simply calculated as the proportion of the negative length occupied by the image multiplied by the real negative width obtained from the calibration curve. In the example above where the real negative width was 2X m at distance Y, the head length is 0.25 x 2X m = 0.5X m. As a point of detail, Webb and co-workers measure the proportion of the negative's long axis occupied by the image using the graticule on the eyepiece of a dissecting binocular microscope.

It is worth noting that the calibration curve which Choquenot and Webb (1987) derive empirically could also be derived mathematically for each lens with the lens formula provided the relationship between the arbitrary distance scale and real distance is known. The advantage of deriving the curve empirically is that it compensates for lenses not being to the manufacturer's stated focal length. The disadvantage is that it introduces the possibility of experimental error into the calibration exercise.

A COMPARISON BETWEEN THE METHODS AND EQUIPMENT

The accuracy obtained with the two methods is similar. Both give estimates ± 5-8% of the real subject size (head lengths of crocodilians, 6-45 cm), using a 200 mm lens within the optimal distances range of about seven m. The methods are also more or less equivalent in terms of ease of use. Both require an initial calibration exercise, one to derive a calibration curve, the other to derive an accurate real distance scale. One possible advantage of retaining the lens formula in the calculation rather than deriving a calibration curve is that the former can accommodate variation in the focal length of the lens. This potentially allows a variable focal length (zoom) lens to be used for the surveys, an advantage when the likely range of subject sizes and approach distances is great. It should be noted, however, that in practice the introduction of the lens focal length as an additional variable produced an error in excess of 10% in laboratory trials on a model subject. Considerable refinement of the zoom lens technique would be required to improve the accuracy, and for the present at least a fixed telephoto lens appears a better choice.

With regard to equipment in general, I found the best combination to be a 35 mm format single lens reflex camera together with a powerful dedicated flash with telephoto adaptor and a 200 mm lens (with rotating polarizing filter to improve image clarity of submerged parts of the subject). It is important that the lens have a long infinity rating and a shallow depth of field at maximum aperture to allow the camera-to-subject distance to be accurately recorded. A drum extension on the focusing ring enables the scale to be more finely graduated and easier to read. The accuracy of the distance scale should be checked before surveys since the focusing ring of a damaged or inferior quality lens may be prone to 'slipping'. Slipping occurs when the lens focusing ring is free to move to some extent without actually changing the focus distance of the lens. This introduces error into the camera-to-subject distance reading. In general there is room for improvement on simply measuring the camera-to-subject distance from the lens focusing ring. Possibly a more sophisticated light beam range finder could be employed for this purpose. The dedicated telephoto flash should ideally have a fast recycling time to allow a series of photographs to be taken in rapid succession during night surveys. Good 'off-flash' rechargeable battery packs provide almost instantaneous recycling and are also more economical for long term studies.

OTHER PHOTOGRAPHIC TECNHIQUES FOR SIZE ESTIMATION

Earlier authors have proposed contrasting techniques for estimating subject sizes with the aid of photography. Unlike the Lens Formula Method and the Calibration Curve Method, these techniques do not depend on the relationship expressed in the lens formula for their basic validity. Parker and Watson (1970) for example used pre-positioned anchored reference markers to calibrate aerial photographs of *Crocodilus niloticus* individuals in the same frame. This technique is excellent for aerial surveys which are essentially "two dimensional" but is not immediately applicable in the many situations where a boat survey is required.

I experimented on a variation of Parker et al.'s technique employing a horizontal rule suspended below a long lightweight pole and positioned over the heads of *M. niger* individuals encountered during night canoe surveys. The method helped place the caiman in broad size class categories during direct observation and could also be used to calibrate photographs in the manner of Parker and Watson. The equipment was unwieldy, however, and it was often hard to place the rule in the same focusing plane as the black caiman. Attempts to use the technique with the more wary spectacled caiman, *Caiman crocodilus*, in Peru, and the Nile crocodile, *Crocodilus niloticus*, in Madagascar were also hindered by the subject frequently submerging in response to the disturbance and even occasionally lunging at the rule!

Gorzula (1984) outlines another type of photographic size estimation technique using snout-length/total-head-length ratios calculated from field photographs to estimate the total snout-vent length of the individual photographed. The technique was suggested for use with *C. crocodilus* but as Webb and Messel (1978) point out, the relationship between these morphometric dimensions appears to change unpredictably with age for a variety of other crocodile species so far studied. It remains to be seen whether morphometric ratios calculated from photographs of other herpetological subjects could be successfully used to estimate the actual size or age of an individual.

OBLIQUE IMAGES - A PROBLEM

An important problem common to all the photographic techniques described is that of length attenuation of dimensions not photographed at right angles to the subject-to-camera line. For *M. niger* it proved easy to approach individuals during surveys and to obtain good photographs perpendicular to the subject-to-camera line using the caiman eyes to align the camera. For other subjects this may be impracticable and Choquenot and Webb (1987) use reference templates of a preserved head photographed at various angles in order to derive a correction factor for non-perpendicular photographs. As they point out, the development of "3D" computer graphics suggests both the possibility and direction of future improvements in this field.

CONCLUSION

The Lens Formula and Calibration Curve methods of photographic size estimation have proved to be practical ways of estimating the size of *M. niger* in Peru, and *C. porosus* in Northern Australia, respectively. The basic principle which underlies these two methods, that of deriving the actual subject size from its image size in the negative given the camera-to-subject distance and lens focal length, is in no way dependent on any feature particular to these species. The general technique is, therefore, applicable to any subject, crocodilian or otherwise. The ultimate choice of lens and accuracy of the technique depends very much on the size and ease of approach of the subject.

For *M. niger* the photographic technique has proved to have an added advantage in that juveniles and sub-adults are individually recognizable from the configuration of large black pigment spots on the lower jaw. Perhaps individuals of other reptilian species will prove to be individually identifiable as well. The ability to recognize individuals without resorting to mark/recapture techniques is especially valuable for crocodilian species which often learn to avoid recapture (Cocroft pers. comm., Webb and Messel 1979). Work is planned to determine how the pattern changes for *M. niger* individuals with age, and whether photographic files of individuals in a

population can be used to identify specimens in long term ecological studies.

ACKNOWLEDGMENTS

I would like to thank Dr. Max Gunther of Peruvian Safaris S.A. for logistical support during my work in Peru; Dr. Grahame Webb for his helpful comments which allowed the first draft of this report to be improved; and two anonymous reviewers.

ANURA

BUFO MARINUS (Marine Toad). **PREDATION.** On 31 October 1987 in savanna woodland close to Alter do Chão Pará, Brasil (2°31'S, 55°00'W) at 0813 h I intercepted a grissón (*Galictis vittata)* entering the forest from the savanna, with a large (ca. 25 cm TL) *Bufo marinus* hanging from its mouth. The grissón stopped within five m of me for about 20 sec. The frog was not collected but as *B. marinus* is the only large bufonid in the area there can be no doubt as to its identity. *Bufo marinus* are extremely common in the area and it is unlikely that the adult grissón had not been exposed to toads before. Rather, it seems that the potent skin toxins of *B. marinus* are not an effective defense against grissóns.

RANA AREOLATA AESOPUS (Florida Gopher Frog). **MOVEMENT.** An adult female *Rana areolata aesopus* (84 mm SVL), marked at the Breezeway Pond on the Katharine Ordway Preserve/Swisher Memorial Sanctuary, four km E of Melrose, Putnam Co., Florida, on 30 March 1987, was caught in a Sherman live trap set at the mouth of an active gopher tortoise burrow on 26 July 1987. The recapture occurred 2.0 km WSW of the Breezeway breeding pond on a disturbed longleaf pine-turkey oak site dominated by planted slash pine. We believe this to be the first documented observation of a long-distance movement for this species. Carr (1940. Herpetology of Florida, p. 64) states these frogs ". . .travel some distance to congregate at widely separated ponds, since I have found them a mile (1.6 km) from water."

CROCODILIA

CROCODYLUS ACUTUS (American Crocodile). **NEST DEFENSE.** In Panama, American crocodiles are known to nest in clearings and to defend their nests from green iguanas (*Iguana iguana*) that sometimes excavate crocodile eggs while nesting (Dugan et al. 1981. J. Herpetol. 15:409-414). Slider turtles (*Trachemys scripta)* occasionally nest in these clearings too, but construct much shallower nests than do iguanas or crocodiles (Drummond 1983. Copeia 1983:529-530). Here we report observations of aggressive behavior by a ca. 3 m crocodile towards *Trachemys* that neared its nest on the small island of Slothia adjacent to Barro Colorado Island, Panama.

Between 4 and 24 February 1988 we observed four instances of nest-defense through a telescope at a distance of 400 m. In the first, the crocodile entered the clearing from the lake and attacked a large *Trachemys*, as the latter moved rapidly out of the clearing into the forest. In a second incident the crocodile entered the clearing, grasped a turtle by the carapace in its mouth, and shook it. The turtle moved a short distance after its release and the crocodile repeated this behavior. Following the second release, the turtle moved at greater speed into the water. In the third case, the crocodile entered the clearing to interrupt a digging turtle by flipping it onto its back. During the next five min, the crocodile bit at the turtle four times while the turtle struggled to right itself. The turtle regained its feet and fled unpursued to the water. In the final incident we noticed a turtle in the clearing moving towards the shoreline. As it slid down the bank, the crocodile surfaced, grasped the turtle in its mouth, and thrashed it back and forth in the water for a period of ca. one min. At this time, another large crocodile (presumably the mate) surfaced and swam toward the first crocodile, which entered the clearing. When we arrived at the nest site by boat several minutes later, the second crocodile swam away and the crocodile in the clearing entered the water and followed. There was no sign of a dead or injured turtle along the shoreline, although three seemingly undisturbed large turtles were visible in the water nearby.

It is curious that despite ample opportunity, the crocodile failed to seriously injure any of these turtles. Unlike iguanas, which nest-defending crocodiles do occasionally kill, nesting slider turtles probably rarely if ever disturb crocodile nests. Apparently, crocodiles defend their nests rather indiscriminately against many intruders. However, both iguanas and turtles that succeed in laying near a crocodile nest may benefit from the crocodile's general defense of the area.

SAURIA

CALLISAURUS DRACONOIDES. (Zebra-tailed Lizard). **FEEDING.** In the state of Sonora, Mexico, populations of zebra-tailed lizards are common in coast areas. Stebbins (1985. Western Reptiles and Amphibians. Houghton Mifflin Company, Boston) mentioned that *Callisaurus* feed upon insects, spiders, other lizards and occasionally plants.

I captured a reproductive male lizard (SVL = 74.05 mm) during the morning in the intertidal zone of the "El Choyudo" beach 107 km SW Hermosillo City on 15 June 1987. This lizard was killed and his stomach examined for food. I found 42 beach hoppers (Amphipoda) and a young crab (Ocypodidae). These items represented 62.5% of the volume of total stomach contents. The lizard and stomach contents have been deposited in the Herpetological Collection of the Ecological Center of Sonora.

I thank Guillermo Lara of the Ecological Center of Sonora for providing information and support for this and other related reports and to Carlos Tena for his encouragement.

Important New Reference Work Now Available!

Middle American Herpetology
A Bibliographic Checklist

Jaime Villa, Larry David Wilson, and Jerry D. Johnson

Middle American Herpetology provides easy and quick access to the current knowledge on the composition and distribution of all species of amphibians and reptiles occurring in Middle America. The entries in the checklist are arranged by species and include references to key literature that will guide the reader to the works that fully describe and illustrate each species. Each entry also indicates the distribution of the species within the region, which is defined to include Southeastern Mexico and the countries of Belize, Guatemala, El Salvador, Honduras, Nicaragua, Costa Rica, and Panama.

In addition, this volume includes numerous illustrations, approximately ninety-six in color, of species that have not been illustrated previously, that have not been illustrated with a photograph of a living specimen, or that have only been poorly illustrated.

About the Authors. Jaime Villa is Associate Program Director at the National Science Foundation in Washington, D.C. He has been editor-in-chief of *Catalogue of American Reptiles and Amphibians* since 1986 and is the author of seven books and approximately seventy-five articles. Larry David Wilson is in the Department of Biology at Miami-Dade Community College. He is Snakes Editor of the *Catalogue of American Reptiles and Amphibians* and the author of over a hundred publications. Jerry D. Johnson is Professor of Biology at El Paso Community College and Adjunct Professor at the University of Texas at El Paso.

SCELOPORUS UNDULATUS HYACINTHINUS (Northern Fence Lizard). **FEEDING.** Prescribed fire is employed as a principal management tool for hazardous fuel reduction, control of undesirable species, wildlife habitat improvement, range improvement and silvicultural treatments on southern national forests. In the Ouachita National Forest in Arkansas and Oklahoma, cool or backing fires are employed in fall, winter and early spring months to enhance habitat for wildlife. These fires typically consume about one-half of the leaf litter, leaving behind the more moist, deeper layer of duff.

On 21 March 1985, during a prescribed burn under a mature shortleaf pine (*Pinus echinata*) and mixed hardwood (*Quercus/Carya*) canopy, an adult northern fence lizard was observed to repeatedly prey on crickets (Gryllidae) advancing a meter ahead of the slow moving backing fire. The lizard, undaunted by the approaching flames, would "perch" on fallen limbs and twigs on the forest floor which provided an elevated view, 10-20 cm above the substrate of the immediate area. Upon observing a cricket emerge from the leaf litter, the lizard would climb down from the perch and seize and consume its prey. The lizard immediately returned to the perch and repeated the process. When flames approached that perch, it was abandoned for a decaying stump. The lizard fed twice more in the same manner and, apparently satiated, retreated to the trunk of a large tree outside the burn area where it remained for ca. 5 minutes before moving out of sight.

Observations of similar opportunistic feeding along the front of a fire by various species of wildlife was summarized by Komarek (1969. Proc., Tall Timbers Fire Ecology Conference, Tallahassee, FL, pp 161-207).

SERPENTES

DRYMARCHON CORAIS COUPERI (Eastern Indigo Snake). **ECDYSIS.** Although aspects of shedding, such as its frequency in captivity, have been reported for many species of snakes, descriptions of ecdysis under field conditions are exceedingly scarce (e.g., Gibbs 1892. Forest and Stream 39(1):7-8). At 1200 h on 8 February 1987, I observed a radiotagged male eastern indigo snake (1170 mm SVL, mass = 520 g) shedding on the Katharine Ordway Preserve-Swisher Memorial Sanctuary, Putnam Co, Florida, in longleaf pine-turkey oak sandhills habitat. The weather was clear and breezy with an air temperature of 25° C.

The snake first was observed crawling slowly through a small brush pile. It moved in rectilinear fashion and did not deliberately use objects to snag or hold the shed skin, which was pulled behind the body. Instead, a series of spasmodic jerks at the point of detachment provided traction with the substrate and allowed the skin to loosen and to fold back and off. When the body moved around or under surface debris, the debris did not provide an anchor to the shed skin. The rest of the body moved in smooth continuous motion, and the snake was alert and tongue-flicking. The shedding sequence took 8 min from when observations began, and I estimate 20-24 min for completion. As shedding neared completion, the snake moved toward and entered a gopher tortoise (*Gopherus polyphemus*) burrow near where he had first been seen; as such, he had traveled in a circuitous loop to a point 5 m from the burrow.

Klauber (1972. Rattlesnakes. Univ. Calif. Press, Berkeley, pp. 355-356) gives probably the best description of the process of ecdysis although the circumstances are not stated. He also noted rectilinear progression during shedding and described a film in which *Crotalus atrox* loosened the skin "by a rippling or caterpillar movement produced by the subsurface muscles at the point where it was being turned back." This may be comparable to my observations of spasmodic jerks, but more observations in natural or natural-like settings are required to determine precise comparative terminology. In captivity, close proximity to stationary objects and general lack of room for horizontal movement may give the impression that snakes require objects to assist ecdysis. This may not be the case under natural conditions, although rubbing the snout on stationary objects may facilitate initial stages of shedding.

ELAPHE CARINATA (Keeled Rat Snake). **REPRODUCTION.** A sexual pair of *E. carinata,* hatched from eggs laid by recently imported specimens, was obtained by the Columbus Zoo 19 February 1984. At accession both were ca. 40 cm SVL. Courtship and attempted copulation were observed intermittently from 13 March through 10 May 1987, with observed copulations occurring on 18 and 24 April and 3 May 1987. At this time the animals had grown to ca. 125 cm SVL (male) and 110 cm SVL (female).

A clutch of 10 eggs laid 20 May 1987 ranged from 62-86 mm along the long axis and from 30-34 mm along the short axis ($\bar{X}$ = 72 x 32 mm). The clutch, which adhered into a single mass shortly after laying, had a total mass of 429 g. A second clutch laid by the same female 15 July 1987 ranged from 53-70 mm x 25-28 mm (n = 8, $\bar{X}$ = 63 x 27 mm) with a total mass of 223 g. Four of the first clutch hatched 7 - 11 July 1987 after 48-52 days incubation at a minimum of 28° C. One of these hatchlings survived less than 72 hours. Four additional eggs opened 12 July 1987 contained dead but fully formed neonates, all of which had cut the eggshell to some extent.

Seven of the eggs from the second clutch hatched 1-3 September 1987 after 48-50 days incubation, also at a minimum of 28° C. The three viable hatchlings from the first clutch ranged from 274-284 SVL (350-363 TL). With the inclusion of non-hatching and non-viable specimens, the eight specimens from the first clutch ranged from 252-284 SVL ($\bar{X}$ = 272.8 mm) 319-364 mm TL, $\bar{X}$ = 347.5 mm). The seven hatchlings from the second clutch ranged from 265-285 mm SVL ($\bar{X}$ = 273.6 mm) and from 338-362 mm TL ($\bar{X}$ = 347.5 mm).

ELAPHE OBSOLETA OBSOLETA (Black Rat Snake). **ANTIPREDATOR BEHAVIOR.** The presence of snakes in the diet of the red-shouldered hawk, *Buteo lineatus,* is well known (May, J.B. 1935. The Hawks of North America. Nat. Assoc. of Audubon Societies, N.Y.). In addition, hawks are known to be major predators of adult rat snakes (Johnson, T.R. 1987. The Amphibians and Reptiles of Missouri. Missouri Dept. of Conservation, Jefferson City, Mo.). The following describes an antipredatory response by a young *E. o. obsoleta* during an attack by a red-shouldered hawk on 19 March 1988 in Fargo, Monroe County, Arkansas.

While we were driving along the levee of a fish pond (T4N,R2W,S23) at 1310 h, an immature red-shouldered hawk was observed landing on the ground at the forest edge. The hawk was opposite the levee which is separated by a ditch. At 1312 h we were ca. 27 m from the hawk and for five minutes observed no movement. Unable to identify the snake from that distance, we decided to rob the bird of its prey. When approached, the hawk made no movement. Closer inspection revealed the anterior quarter of a male *E. o. obsoleta* (90 cm SVL) entwined in the bird's feet.

The snake's neck and head were free and swaying from side to side with its mouth fully gaped. The posterior third of the snake was wrapped twice around the hawk's neck. The bird's mouth was open and its head was drawn close to its feet. The hawk was clearly fatigued and did not struggle as both were disengaged.

In attempts to separate the pair, the snake twice rewrapped itself around the hawk's neck in similar fashion while chewing on the bird's leg. Once separated, the hawk assumed a defensive posture on the ground. After we left, the bird perched nearby. The only visible wound on the snake was a skin tear ca. 4.5 cm behind its head.

The apparent success of this young *E. o. obsoleta* to at least partially deflect a hawk attack may be due to a combination of the inexperience of the immature hawk and the use of constriction as a defense by the snake.

Submitted by **W. E. MESHAKA, S.E. TRAUTH** and **C. FILES.** WEM and SET: Department of Biological Sciences, Arkansas State University, State University, AR 72467. CF: P.O. Box 193, Hunter, AR 72074, USA ●

HYPSIGLENA TORQUATA JANI (Texas Night Snake). **BEHAVIOR.** Various antipredator behaviors have been described for *Hypsiglena torquata* (Mitchell 1985. Herp.

Review 16(2): 54, 56; Hayes 1985. Herp. Review 16(3):79, 81; Price 1987. Herp. Review 18(1):16). A male *H. t. jani* (293 mm SVL) from near Santa Rosa, Guadalupe Co., New Mexico, has been maintained in captivity since May 1986 and has exhibited protean behavior unreported for the species.

When initially startled the snake usually assumes a rigid, sigmoid posture, often with short segments of its body slightly elevated above the substrate. Motion or physical contact by the observer causes the snake in this posture to flex violently ("snap") its body once, reversing the orientation of its body curves. The action is often accompanied by a brief hiss and occasionally by cloacal discharge, and is often sufficiently forceful to lift the snake from the substrate. The rigid, sigmoid posture is usually reattained and additional stimuli often yield several repetitions of the behavior. More typical defense behavior (thrashing) is initiated after prolonged disturbance or if the snake is grasped.

This "body snapping" is comparable to act systems #62-63 of Carpenter and Ferguson (1977. pp. 378-399, *In:* Gans and Tinkle, Biology of the Reptilia 7, Academic Press). Similar behavior has been reported for *Micrurus fulvius* (Gehlbach 1970. Herpetologica 26(1): 24-34), and may occur with varying frequency in many snake species with diverse defense behaviors (Humphries and Driver 1970. Oecologia 5(4):285-302).

Submitted by **JAMES N. STUART,** U.S. Army Corps of Engineers, Environmental and Evaluation Section, P.O. Box 1580, Albuquerque, NM 87103, USA ●

MEHELYA CAPENSIS CAPENSIS (Cape File Snake). **BEHAVIOR.** This snake virtually never bites and its only documented form of defence is the voiding of the foul-smelling contents of the cloacal glands (Broadley and Cock 1975. Snakes of Zimbabwe. Longman, Zimbabwe. 152 pp.). Another form of defence is detailed here.

On 22 May 1987, at Moeding College, Otse, Botswana (25.02 S: 25.45 E), at 1750 h, ca. 3 min before sundown, a juvenile *M. c. capensis* was observed crossing a path in savanna (this is itself unusual as *M. c. capensis* is regarded as a nocturnal snake; see Broadley 1983. Fitzsimons' Snakes. Delta Books, Cape Town. 376 pp.). When approached, it coiled up suddenly, hiding the head under the coils, and refused to emerge when prodded with a finger, although it vibrated the coils. Similar behavior has been noted in snakes of the genus *Prosymna* (Broadley 1983, op. cit.) but not *Mehelya*. The snake was deposited in the collection of the Department of Wildlife and National Parks, Gaborone, (H 5370).

Submitted by **STEPHEN SPAWLS,** Moeding College, Private Bag 11, Lobatse, Botswana. ●

OPHEODRYS AESTIVUS (Rough Green Snake). **ANTIPREDATOR BEHAVIOR.** On 25 February 1986 at 1015 h I observed an object fall from the tree canopy in Mahogany Hammock, Everglades National Park, Florida. The object, a small *O. aestivus*, had fallen from a height of at least 4 m. Immediately a blue jay (*Cyanocitta cristata*) flew from where the snake had fallen and landed on the ground next to the snake. The jay pecked repeatedly at the snake, which thrashed vigorously, apparently attempting to crawl away. Periodically the snake turned and struck at the jay. After 1-2 min the snake wrapped itself tightly around a stick (ca. 20 cm long) that was lying nearby. The jay continued its attack by biting the snake's head several times. A red-bellied woodpecker (*Melanerpes carolinus*) landed next to the jay, which then grasped the stick in its bill and flew ca. 20-25 m and landed on the ground. The snake remained wrapped around the stick during the flight. After landing, the jay dropped the stick and renewed its attack, pecking strongly at the snake (still wrapped around the stick). The jay's pecking moved the stick and snake several cm into dense vegetation so I could not observe the outcome of the attack. No blood was evident on the snake's body when it was last seen.

By wrapping itself around an object or by forming a "knot" in its body (Yeatman 1983. Herp. Review 14:22), a snake may prolong the predatory attempt and enhance its probability of survival under certain circumstances. My field experience in capturing snakes suggests to me that knotting the body around an object after being grasped may be a widespread behavior in both constricting and nonconstricting species.

Submitted by **GEOFFREY A. HAMMERSON,** 46 Kelsey St., Middletown, CT 06457, USA ●

OXYBELIS AENEUS (Brown Vine Snake). **BEHAVIOR.** Distribution of *O. aeneus* in the United States is limited to the Pajarito and Patagonia Mountains in extreme southern Arizona, and recent records of this species are rare. Here we report a sight observation and unusual predatory behavior of *O. aeneus* with *Sceloporus clarkii* and *Urosaurus ornatus* in Sycamore Canyon, Pajarito Mountains, Santa Cruz County, Arizona.

On 20 May 1988 at 0900 h, 0.16 km downstream from the trailhead at Hank and Yank Spring in Sycamore Canyon ca. 1216 m elevation, we observed an *O. aeneus* draped in a tangle of *Quercus* sp. branches 1.7 m above ground. Most of the 53 cm (SVL) snake was entwined among branches, but anteriorly, 30 cm was horizontally suspended in midair. In its jaws was the head of a live 5 cm (SVL) *U. ornatus*, whose hindlimbs were in the jaws of a 10 cm (SVL) *S. clarkii* perched on a nearby branch. The trio remained frozen in this position 10 min, with the *O. aeneus* and *S. clarkii* on separate branches and the *Urosaurus* bridging the two.

The *Sceloporus* finally moved to the back side of its branch, taking the *Urosaurus* and pulling with it the suspended portion of the snake. Out of view, the *Sceloporus* lost its grip on the *Urosaurus*, and the snake returned to its original position with the motionless *Urosaurus* dangling from its mouth, now enveloped to the ears. They remained in this position when we left 10 min later. The *S. clarkii* did not return during this time, nor did we ever observe any antagonistic behavior between it and the snake. It appeared that the snake had eaten earlier as it had a small bolus in the upper third of the digestive tract.

TYPHLOPS BRAMINUS (Brahminy Blind Snake). **RATTLING.** Many tropical Asian snakes rattle effectively by vibrating their tails just as do their American counterparts. I have observed tail vibration in Asian viperid *Trimeresurus* and colubrid *Elaphe* and *Coluber* ("Ptyas"). Rattling and its evolutionary significance are discussed by Carr (1963. Reptiles. Time-Life Inc., New York. pp. 61-62). Because of its remote phylogenetic position, fossorial habits, and miniscule size I was taken aback to repeatedly observe an adult female *Typhlops braminus*, ca. 14 cm SVL, vibrate its tail in typical rattling form at Keung Shan catchwater, Lantau, Hong Kong Territory, 17 April 1987. In my field catalog (p. 117) I note that this individual vibrated its tail so strongly as to shake the entire posterior third of the body. Others observing this behavior included herpetologists S.J. Karsen and M. Wai-neng Lau, mammalogist N.C. Goodyear, and six Earthwatch participants. Locally this is the "most abundant of all snake species" and "extraordinarily abundant" (Karsen, Lau, and Bogadek 1986. Hong Kong Amphibians and Reptiles, Urban Council, Hong Kong. p. 68). We have a large series at Museum of Comparative Zoology from Lantau and therefore did not collect this specimen. My field work was supported by Earthwatch and The Conservation Agency.

TESTUDINES

CHRYSEMYS PICTA (Painted Turtle). **PREDATION.** Predation of juvenile and adult freshwater turtles has been little studied and is generally considered a normal source of population loss. In certain cases, predation of juveniles and adults may represent a substantial loss to a population.

On 15 April 1987, I collected 44 *Chrysemys picta* and one *Chelydra serpentina* carcasses within 15 m of the perimeter of four small (total 0.9 ha) wetlands in the Petenwell Wildlife Area (T18N, R4E, Sec. 2 and 10), Adams County, Wisconsin. Habitat descriptions are found in Ross (1985. M.S. Thesis Univ. Wis.-Stevens Point). All turtles appeared to have been killed and most were eaten by raccoons (*Procyon lotor*) in the manner described by Wilbur (1975. Ecology 56:64-77.) Many individuals (24, 55%) were juveniles ≤80 mm PL. Many individuals were freshly killed, other carcasses may have been one to three weeks old. A two-year study estimated the population at 164 (range = 138-201) *Chrysemys.*

The Catalogue of American Amphibians and Reptiles

Announces the Publication of the

Index

to Accounts 1-400

• The **Catalogue of American Amphibians and Reptiles** is *the* archival publication on the amphibians and reptiles of the Americas, covering species from North, Central, and South America, as well as the Caribbean. Accounts of over 400 taxa, most North American, have been already published. Yearly 20 or more accounts are published, ranging from one to four pages each.

• As the *Catalogue* is in its 25th year, the publication of a comprehensive index was long overdue. The ***Index*** contains a cross-referenced listing of all taxa included, as well as their synonyms. It will undoubtedly make usage of the *Catalogue* much easier.

• If you are not a *Catalogue* subscriber the ***Index*** may still be useful by itself, and you may wish to purchase it separately. You may also obtain it, *free*, with your 1988 *Catalogue* subscription.

So, if you are not a subscriber, now is the time!

Subscription rates (1988) are: **Individual: $ 10**
Institutional: $ 15
Deduct $ 1.50 for pre-paid subscriptions (i. e., no invoicing required)

Index Only: $ 5.00 (pre-paid)

TO ORDER your copy of the ***Index***, or to subscribe to the *Catalogue*, contact:
Dr. Douglas H. Taylor, SSAR Treasurer. Department of Zoology,
Miami University. Oxford, OH 45056 USA

Society for the Study of Amphibians and Reptiles

These wetlands are deeper (0.5-1.8 m) than most of the surrounding wetlands and both *C. picta* and *Emydoidea blandingi* appear to congregate within them for overwintering; thus, a concentrated population is present upon spring emergence. Perhaps the concentrated nature of the population causes predators, such as raccoons, to home in on the area. Removal of 26% of the *Chrysemys* population over such a short period is greater than that estimated in other studies. Wilbur (op. cit.) and Tinkle et al. (1981. Ecology. 62:1425-1432), studying the same Michigan population, believed mortality of post-nest juveniles and adults was <10% and near 15%, respectively. Nest predation and mortality, however, are important sources of population loss and are usually higher than that of post-nest juveniles (Snow 1982. Can. J. Zool. 60:3290-3292, Breitenbach et al. 1984. Herpetologica 40:76-81). An early spring in central Wisconsin may have permitted *Chrysemys* to begin activity early and their basking on the banks of the wetlands (few basking sites disjunct from shore exist) probably permitted easy predation by raccoons. Also, during late March and early April, less food resources are available to raccoons, and turtles are a locally abundant alternate food source.

I thank J.D. Congdon for comments on this note.

CLEMMYS MARMORATA (Western Pond Turtle). **BEHAVIOR.** Information on aspects of reproductive activity in *Clemmys marmorata* is confined to incidental notes on oviposition (Storer 1930. Univ. Calif. Publ. Zool. 32:429-441; Feldman 1982. Herp. Review 13:10-11). Copulation has been observed in the field in mid-June in Southern California and in captive specimens in late August and early September. Herein I report on possible courtship behavior in this species.

Observations were made at Arroyo de la Cruz, San Luis Obispo Co., California from 1242-1247 h on 30 August 1987. Two turtles, a 159 mm CL male and a 147 mm CL female were observed in 2 m of water (surface temp. 19° C, bottom temp. 16° C). When first observed, both turtles were moving slowly along the bottom. The female had retracted the head and the limbs were partially extended. The male swam to one side 4-5 cm behind and slightly (2-3 cm) above the female, with the head and limbs fully extended. The male made several scratching motions at the anterior left edge of the female's carapace with his right front foot. The female stopped, retracted the front limbs and elevated the posterior portion of the shell 2-3 cm off the substrate by extension of the hind limbs. The male swam to the front and facing the female, made 17 scratchings at the anterior edge of the carapace with one or both front limbs. The head was extended and came in contact with the female's carapace four times, although biting was not observed. The male then moved to a position 15-20 cm in front of and slightly to the left of the female, fully extended the head and partially extended the left front and left rear legs. Several short (<2 cm) horizontal

Prepublication Announcement

AN ANNOTATED LIST AND GUIDE TO THE AMPHIBIANS AND REPTILES OF MONTEVERDE COSTA RICA

BY

Marc P. Hayes, J. Alan Pounds and Walter W. Timmerman

A field list and guide for the 154 amphibians and reptile species known from the Monteverde region of Costa Rica. Fifty-eight amphibians (2 caecilians, 5 salamanders and 51 frogs) and 96 reptiles (26 lizards and 70 snakes) are described and keys for identifying families and species are provided. Annotations on habitat, reproductive mode, and local distribution are made for each species. Approximately 45 pages with 32 photos.

Prepublication price $4.00
After Jan. 30, 1989 .....$5.00

Orders may be sent to Douglas H. Taylor Dept. of Zoology, Miami Univ., Oxford, Ohio, 45056 USA.

coordinated sweeping/fanning movements were observed. This behavior lasted approximately 25 sec. The scratching behavior previously described was repeated, with 22 movements of one or both limbs. The male again swam to the same position in front of the female and repeated the limb-sweeping behavior for a period of 15 sec. The male then elevated the entire body at a 45° angle directly in front of the female and fully extended the head and all limbs. This behavior lasted ca. 20 sec.

At the termination of this activity, the male surfaced for air within 1 m of the observer. After 35 sec he dove to the bottom a short distance from the female and swam off a distance of 1 m, then returned to the female briefly (<10 sec) before turning and swimming to within 40 cm of the observer, whereupon he turned rapidly and attempted to escape.

Submitted by **DAN C. HOLLAND,** Department of Biology, University of Southwestern Louisiana, Lafayette, Louisiana 70504-2451, USA ●

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **MIGRATION.** The leatherback sea turtle is the largest and most pelagic of extant sea turtles. It is also distinguished by the most extensive geographic range of any reptile, with the northernmost recorded latitude being approximately 71° N, and the southernmost approximately 27° S (Pritchard and Trebbau 1984. Turtles of Venezuela. Society for the Study of Amphibians and Reptiles.). Nonetheless, our knowledge of the distribution and movement of leatherbacks is scant. Records of adult leatherbacks away from known nesting grounds consist of opportunistic sightings at sea, incidental catch in fishing gear, and the stranding of dead or dying animals in coastal areas.

The paucity of information regarding the migratory movements of adults makes any stranding of a tagged individual particularly valuable. The first such record is available from Hughes (1974. The sea turtles of southeast Africa II. Investigational Report 36, Oceanographic Research Institute, Durban, South Africa), who reported that an adult female leatherback traveled some 1000 km north to Mozambique after nesting in Tongaland, Natal, 369 days earlier. Pritchard (1976. Copeia 4:749-754) provided additional evidence of long-distance movement when six leatherbacks tagged in French Guiana and Suriname were recaptured as far away as New Jersey (USA) and Ghana (West Africa). Five of these individuals had traveled distances exceeding 5000 km, thus marking the longest migrations on record for any reptile (Pritchard 1976. Copeia 4:749-754).

More recently, a leatherback tagged "T 16" while nesting at Matura Beach, Trinidad, in May 1970, was later recorded nesting at Tacarib Bay, Trinidad, in April 1975 and then reported dead in September 1977 on Rockaway Beach, New York (Lambie 1983. Marine Turtle Newsletter 24:17). This stranding lends credence to the contention that Caribbean-nesting leatherbacks journey into temperate latitudes (e.g., Bleakney 1965. Can. Field-Nat. 79:120-128; Lazell 1980. Copeia 1980 (2):290-295). However, since the stranding occurred more than two years after the last documented nesting, the incident offers no direct evidence of post-nesting movement.

We now provide the first direct evidence that leatherbacks nesting in the West Indies may engage in migratory movements northward immediately following the nesting season. A 245 kg leatherback tagged "AAG 313" on Sandy Point, St. Croix, United States Virgin Islands, was last seen nesting on Sandy Point on 8 June 1981. She was recovered 85 days later on 1 September 1981 in Surf City, New Jersey, an intervening distance of 1680 nautical miles (3113 km). Death was attributed to blockage of the ileocaecal valve by a large, clay-like mass (enterolith) (R.C. Schoelkopf, pers. comm.).

PSEUDEMYS NELSONI (Florida Red-bellied Slider). **MUTUALISM.** Control of epizoophytic growth on the carapace of turtles may be achieved by basking or, as in some cases, the turtle may actively bite algae off its own shell (Reilly 1983. Herp. Review 14(3):76). The following documents an instance in which algal growth is removed by the actions of a conspecific.

On 28 December 1987 at 1330 h along a canal parallel to SW 344 St. 2 km E of US Hwy 1, Miami, Dade County, Florida, a female *P. nelsoni* was observed eating algae from the carapace of a male conspecific for ca. four min. before being startled. The male and female were ca. 22.0 and 28.0 cm CL, respectively. Both were nearly horizontal and just under the surface of the water 0.5 m from the shore. The male remained passive, clinging to floating debris with head above water while periodically changing his direction of view. The female behind the male, at all times held the male's carapace with her forelegs. Algae was seen only on the posterior region of the carapace and was sheared with bites by the right side of the female's mouth. Twice, the male was pulled under the water by the actions of the female. The male readjusted his position making no attempt to leave. During the course of my observation, the female surfaced twice and only momentarily. After being detected, the male quickly swam away leaving the female to remain motionless for ca. one min. before surfacing a third time. Shortly after, she slowly swam away.

While algal growth may afford turtles a certain amount of camouflage, in excess, shell deterioration and death can occur (Neil and Allen 1954. Ecology 35:581-584). The behavior reported here suggests a mutualistic relationship. By utilizing a convenient food source, both turtles benefited. This might be particularly beneficial in situations where turtles are unable to bask enough to adequately control algal growth.

Submitted by **WALTER E. MESHAKA JR.,** Department of Biology, Arkansas State University, State University, AR 72467, USA ●

BOOK REVIEWS

The Cold-blooded Australians, by Gunther Schmida. 1985. Doubleday Australia Pty. Limited. 208 pp. $24.95 Australian.

"Exemplary" is the single word that best describes the photography in this all color "coffee-table" book.

Until now the author has, perhaps, been best known to enthusiasts of the aquarium industry through his pictorial contributions to the various aquarium journals. In *The Cold-blooded Australians* he has continued with his pictorial concept. However, to the fish, represented by some 65 photos, he has added another 165 photos of the herpetofauna and more than 40 photos of their various habitats.

Rather than using systematic groupings, Schmida has opted for a geographic approach, dividing the country into eight drainage regions. While a taxonomist might take exception to such an unwieldy format, those for whom the book was primarily designed (laymen to advanced amateurs) are unlikely to complain. Certain of the inevitable overlaps have been discussed both in the introduction and respective chapters.

Intended as a "unique photographic study," the book accomplishes this and more. While the captions are often short, they include common and scientific names, size, food, and the most noticeable characteristics of the species being discussed. The final chapter is a rather cursory explanation of Schmida's photographic techniques and the equipment used.

Given the confused state of the Australian herpetofaunal taxonomy, the nomenclatorial designations for both these and the fish are remarkably current. However, a request to suppress the generic name *"Bothrochilus,"* used in the book and current for the members of what has long been known as "*Liasis*," has been tendered to the International Commission on Zoological Nomenclature. Similarly, a request to return the various carpet snakes and amethystine python (and certain others) to the genus "*Morelia*" (which Schmida has used, somewhat prematurely, in his book) from the current designation of *Python* is being currently entertained. And it would have been better to say "this morph" rather than "this species" in the caption concerning the Atherton Tableland carpet snake (p. 44) when mentioning its currently questionable taxonomic status. Finally, the name *"praelongus,"* recently resurrected from the synonymy of *antarticus* upon very tenuous characteristics, now seems likely to soon be again relegated to obscurity.

The above criticisms are minimal when the book is viewed in its entirety. Certainly it is worthy of a place in the library of any professional or amateur naturalist who has even a cursory interest in these, *The Cold-blooded Australians*.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SSAR BUSINESS

SSAR/HL FUTURE MEETING SITES

The Joint SSAR/HL Meeting Sites Committee is planning future annual meetings. Any SSAR or HL members who are interested in hosting a meeting should contact Henry R. Mushinsky. I will help you organize a meeting on your campus. Hosting a meeting can be a very rewarding experience, and is also an invaluable service to the societies.

Further information may be obtained from Henry R. Mushinsky, Department of Biology, University of South Florida, Tampa, FL 33620, USA. ●

LIFE MEMBERSHIPS

SSAR is once again offering two membership plans which benefit both the Society and participating members.

Life memberships are now available for U.S. $600. This may be paid in a lump sum or distributed over three years, at $200 per year.

Three-year memberships are also available, guaranteeing membership at 1989 rates in the event of a subsequent dues increase.

Both options will appear on the dues envelope which you should receive shortly. ●

SPONSORSHIP OF NON-U.S. MEMBERS

SSAR is expanding its sponsorship of non-U.S. members by requesting contributions to a fund established to defray the membership dues of herpetologists in countries that face difficulties with exchange of foreign currency. We encourage your participation in this program. Your 1989 dues envelope will afford you the opportunity of supporting a specific individual or the general program. You may also contact our Treasurer, Douglas Taylor, if you can assist in the identification of colleagues who can benefit from this program. ●

WANTED: MEMBERSHIP SECRETARY

The Society is embarking on a major membership campaign to attract new members from the large pool of individuals at colleges, universities, secondary schools, museums, zoos, nature centers, and regional herpetological societies. A "Membership Secretary" is being sought to coordinate this effort. The volunteer will receive financial and logistical support from the Society as well as assistance from the officers and directors. Further information is available from Hugh Quinn, SSAR President. ●

SSAR CONSERVATION COMMITTEE

The Conservation Committee for 1988-89 consists of the following persons: Nat B. Frazer (Chair), John L. Behler, William S. Brown, William E. Cooper, Dale R. Jackson, Tom Johnson, Tom Langston, Paul E. Moler, and Rich Seigel. Conservation-related matters should be sent to the Chairman at: Department of Biology, Mercer University, Macon, GA 31207, USA. ●

SSAR GRANTS-IN-HERPETOLOGY

The Society for the Study of Amphibians and Reptiles announces that proposals are now being accepted for the 1989 Grants-in-Herpetology Program. This program is designed to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. In keeping with the Society's goal of encouraging participation of the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR. Applicants are limited to submission of one proposal in one category per year. Further, if proposals in any of the categories are not forthcoming, or are judged not to be sufficiently high quality, the funds in those categories may be transferred to the remaining categories.

Grant proposals will be considered in the following categories:

1. REGIONAL HERPETOLOGICAL SOCIETY PROGRAMS OR PROJECTS. Proposals may address educational projects, speaker's fees, regional research, defrayment of one-time-only costs (e.g., money to complete the purchase of a word processor for improvement of a society newsletter), or other purposes that would strengthen regional societies. Proposals may be submitted by regional herpetological societies or by individual members and must be accompanied by a letter of support from the current president of the regional society.

2. HERPETOLOGICAL RESEARCH OR EDUCATION IN ZOOS. Proposals may address any herpetological endeavor conducted in zoos, such as improvement of displays, husbandry, or behavioral research. A letter from the director or herpetological curator of the sponsoring zoo must accompany the proposal.

3. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species. Proposals must be from individuals only and must be accompanied by a letter of support from another member of the SSAR.

4. GRADUATE STUDENT RESEARCH IN HERPETOLOGY. Proposals may address any herpetological research endeavor and may be submitted by individual graduate students only. Applications must be accompanied by a letter of support from the student's major advisor or committee chairperson.

Each proposal must include the following: (A) BACKGROUND AND OBJECTIVES of the proposed project; (B) METHODS of carrying out the project; (C) BUDGET, which should not exceed $500; (D) BRIEF RESUME of the applicant or project coordinator; and (E) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed five pages, excluding resume and budget.

Applicants must designate to which of the four categories their proposal is submitted. All proposals must be submitted in duplicate and postmarked no later than 31 January 1989. Failure to meet the guidelines may result in elimination of a proposal from consideration. The awards will be announced by 1 April 1989. Successful applicants will be expected to submit to the SSAR a written report of the result of this support within a reasonable amount of time after the project year is completed. They are also encouraged to submit the results of research projects for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR.

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number of awards in this program. Your tax-deductible contribution to this program will benefit directly meritorious research and education in herpetology. Contact the President of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to

the Grants-in-Herpetology Program.

Submit proposals or questions regarding application procedures to:

NEWSNOTES

SUPPORT FOR GRADUATE STUDENT TRAVEL TO THE FIRST WORLD CONGRESS OF HERPETOLOGY

The Student Travel Fund Committee (representing The Herpetologists' League, American Society of Ichthyologists and Herpetologists, and Society for the Study of Amphibians and Reptiles) solicits applications for travel grants from doctoral students in herpetology who are currently members of one of the three societies listed above. These travel grants must be used for attendance at the First World Congress of Herpetology and will amount to the equivalent of round-trip air fare from New York to London

The application must be accompanied by a letter of endorsement from the student's advisor. That letter should include a brief evaluation of the past academic record, current status and future potential of the applicant.

Interested students must submit a short proposal (no more than three double-spaced typed pages) indicating: nature of graduate research, career goals, benefits expected from attending the Congress, availability of other supporting funds, and the title and abstract of the poster to be presented at the Congress. Letters of endorsement and student proposals must be received no later than 2 November 1988. Announcements of awards will be made by 15 January 1989. Application materials should be sent to:

COLLECTIONS TRANSFERRED TO AMERICAN MUSEUM OF NATURAL HISTORY

One of the responsibilities of major museums is to accept and incorporate worthwhile systematic collections from other institutions when such collections are deemed out of scope or otherwise surplus by a current repository. With the burgeoning bureaucracy making it ever more difficult to obtain specimens in the field, it is important to see that no specimens of value are lost due to indifference or neglect.

In recent years the AMNH has accessioned and cataloged two important collections donated by institutions whose authorities recognized that the potential for continued care, greater accessibility and future usefulness to systematics would be enhanced by transfer to AMNH. The purpose of this newsnote is to announce that these transfers have been completed, with all specimens cataloged and incorporated in the AMNH collection.

The Newark Museum, Newark, New Jersey: 2860 amphibian and 109 reptile numbers. The eastern United States and New Jersey in particular are best represented, with the collection being rich in larval anurans documenting publications by Kenneth L. Gosner and Irving H. Black. Mr. Gosner (formerly Curator of Zoology, Newark Museum) and Director Samuel C. Miller are gratefully acknowledged for arranging this transfer.

Virginia Polytechnic Institute and State University, Blacksburg: 3523 amphibian and 390 reptile numbers. This varied collection emphasizes Virginia and the southeast. Prof. E. R. Stout (head, Department of Biology), Dr. Joseph Mitchell and Mr. Christopher Pague all played important roles in relocating the collection to AMNH. ●

SNAKE ECOLOGY GROUP

The Snake Ecology Group is an informal network of persons working with snakes in some professional capacity (e.g. governmental agencies, museums, universities, and zoological parks). For our purposes, "snake ecology" has been defined quite broadly, so as to include related areas of behavior, functional morphology, and physiology. The main objective of the Snake Ecology Group is to facilitate and encourage communication among its members.

The first step taken towards this objective has been the compilation of a Directory containing members' names, addresses, phone numbers, areas of interest, current projects, and recent publications. The 34-page Directory was mailed to over 130 participants worldwide in November 1987. As a second step, a more typical "newsletter" was distributed in June 1988. Included in the newsletter are about 30 additions to the Directory, a request for information on underwater hibernation, an open letter on conservation, and two informal discussions (one on radiotelemetry, another on reproductive ecology).

If the Snake Ecology Group is of interest to you, or if you wish more information, please contact A. Ralph Gibson, Department of Biology, Cleveland State University, Cleveland OH 44115-2403, USA [phone (216) 687-2438] or Charles R. Peterson, Department of Biological Sciences, Idaho State University, Pocatello, ID 83209, USA [phone (208) 236-3765]. ●

Important New Book

DICTIONARY OF AMPHIBIANS AND REPTILES

by Natalia B. Ananjeva, Leo P. Borkin, Ilja S. Darevsky and Nikolai L. Orlov

This outstanding new dictionary was issued in Moscow in June 1988. The largest section (370 pages) is a **complete list of the world's amphibians and reptiles** (over 12,000 entries), giving for each family, genus and species the scientific name, author, a brief statement of distribution, and the common names in several languages. There are detailed indexes in Russian (60 pages), English (30 pages), German (20 pages), and French (10 pages), plus an extensive index to the Latin names, both generic and specific (60 pages). The book is excellently printed and is clothbound in a handsome edition; total length 560 pages.

This book contains the only complete listing of the world's herpetofauna available in any language and is an invaluable index for professional herpetologists and serious amateurs alike. Only a limited number of copies are available and are being offered as a contribution to the World Congress of Herpetology by Soviet herpetologists. While supplies last, they may be ordered from *Kraig Adler, Cornell University, Mudd Hall, Ithaca, New York 14853, USA*. Cost is $30 including surface postage. Make checks to "World Congress of Herpetology"; payment in advance.

IN MEMORIAM

THE ROZELLA SMITH FELLOWSHIP FUND

Rozella Pearl Blood Smith, well known figure among herpetologists, died 15 December 1987, after a protracted illness.

Diversely talented, Rozella Smith was an outstanding expert in many fields of thought and endeavor—she was a most catholic scholar with many skills. Her quick wit, articulate expression, energy and vivacity made memorable every association with her. In every way she was a very special person.

Rozella Smith's manual dexterity and logical, mathematical mind were phenomenal, and were applied in many ways. Although her direct and indirect contributions to knowledge were many, through numerous associates, certainly her greatest impact was upon herpetology, in which field she contributed some 72 articles and books (see the Great Basin Naturalist 1988, 48:180-187); others are in press or in final stages of preparation.

Dr. Smith (she received an honorary D.Sc. degree from the University of Colorado in 1982) developed probably the most effective data-retrieval system ever utilized in herpetology or related fields, and applied it with great originality, enthusiasm, and energy to the massive files accumulated by her husband on the herpetofauna of Mexico. Only through her diligent and innovative manipulation of some 150,000 basic index cards derived from about 11,000-12,000 works were the six volumes of the Synopsis of the Herpetofauna of Mexico produced from 1971 to 1980. In that process she prepared literally millions of punch cards; many analyses were never published or used. Her system was applied in a few other contexts, but its full potential was never realized because her deteriorating health coincided with the demise of punch cards, which were the primary vehicle for her system.

Rozella was probably handicapped during her life, in realization of and recognition for her capabilities, through the same social structure that limits many talented women. Therefore, a unique and perpetual academic memorial to Rozella Smith has been established at the University of Colorado. This memorial, which consists of a named graduate fellowship, will be administered by the University of Colorado. In harmony with Rozella Smith's own principles and achievements, this Fellowship will be dedicated to academic excellence. Commitment of institutional and private funds has already been substantial, and promises to make the Rozella Smith Fund the largest and most prestigious of endowments in environmental biology at the University of Colorado.

We solicit contributions to the Rozella Smith Fund from friends and admirers of Rozella Smith, or from those who would support this worthy project. Contributions can be sent to the Rozella Smith Fund at the address given below.

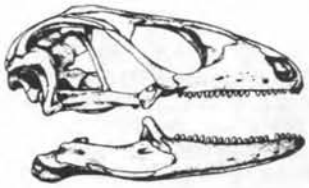
LEGISLATIVE ALERT

The following species have been declared Endangered in Virginia by the Department of Game and Inland Fisheries: *Ambystoma tigrinum, Plethodon shenandoah, Clemmys muhlenbergii,* and *Deirochelys reticularia.* This protection is effective as of 1 October 1987. Virginia law prohibits the collection, possession, transportation, and selling of any individuals of any designated Endangered species, without the appropriate permit. ●



MEETINGS

FIRST WORLD CONGRESS

The First World Congress of Herpetology, to be held at the University of Kent at Canterbury, 11-29 September 1989, promises to be the largest herpetological meeting ever held, with over 2000 enquiries from over 60 countries. Many people have provisionally registered already, but *if you want to be sure of a place, please complete the registration form now* and mail it without delay. There are places for 1000 delegates and 600 accompanying partners and there is every indication that we will easily exceed this number of applications.

Every conceivable topic is covered by our scientific programme whether you are most concerned about conservation, taxonomy, advances in behavioural and evolutionary ecology, or the problems facing herpetological field research, to name but a few areas in the 44 symposia, roundtables and workshops. The poster sessions are a prominent and

Phylogenetic Relationships of the Lizard Families

ESSAYS COMMEMORATING CHARLES L. CAMP

Edited by Richard Estes and Gregory Pregill. Using modern analytical methods of phylogenetic systematics, this is the first comprehensive treatment of the relationships among lizard families to appear in over 50 years. In chapters by the leading experts on particular squamate taxa or anatomical systems, it brings together a vast body of information intended both for systematists and for biologists who know the value of interpreting organismal biology and evolution against a historical background. Illustrated with some 180 drawings and photographs. 648 pages. $75.00

Stanford University Press
STANFORD, CA 94305

important part of the Congress and I do urge you to consider sending a completed abstract form to the posters manager. If you want to present a spoken paper, send the abstract form to the senior convenor of the appropriate symposium (addresses given inside the meeting booklet which was provided at the annual meeting and in response to inquiries). *The deadline for volunteering to present an oral paper is 1 November 1988.*

Many trips and tours are planned for those who want to see the U.K., Europe, and other parts of the world, and the Congress has an extensive social programme. Everybody will find something relevant to their interests and concerns, and all will be welcome.

The (in)famous SSAR auction, Joseph T. Collins, presiding, will also be part of the programme. In order to save on baggage costs, please *mail* all auction items directly to me well in advance of the meeting. Due to time limitations, only three hundred items will be offered so please restrict your contributions to those you consider most valuable or saleable.

Complete registration circulars, for those residing in North, Central or South America, may be obtained by writing to the editor of *Herpetological Review*. Inquiries from other parts of the world may be sent directly to me.

SOCIETY FOR RESEARCH ON AMPHIBIANS AND REPTILES IN NEW ZEALAND

The inaugural meeting of The Society for Research on Amphibians and Reptiles in New Zealand (SRARNZ) was held on 17-18 October 1987 in Wellington, New Zealand. Thirty-four people attended and apologies were received from 29 in New Zealand and 12 from overseas. Participants gave five-minute presentations about themselves and their interests and many spoke longer on their recent research. The meeting approved a constitution and aims of the Society, which are to:

1. Promote the scientific study of all aspects of the biology of the amphibians and reptiles in the New Zealand region; and
2. Promote the conservation of the indigenous amphibians and reptiles of the New Zealand region.

Two invited addresses were presented before the dinner: Dr Phil Millener, National Museum of New Zealand: "The Latest in N.Z. Paleoherpetology." Dr Michael Thompson, Victoria University of Wellington: "The Latest in Tuatara Research."

The meeting was followed by a field trip to Cape Turakarae, the site of long-term research on lizards, and a barbeque at Rimutaka State Park.

Membership is open to anyone and further details can be obtained from Dr Charles H. Daugherty, President, Zoology Department, Victoria University of Wellington, Private Bag, Wellington, New Zealand; or Mr Donald G. Newman, Secretary, c/- Science Directorate, Department of Conservation, P.O. Box 10420, Wellington, New Zealand. ●

SOCIETIES

CENTRAL FLORIDA HERPETOLOGICAL SOCIETY SCHOLARSHIP

The Central Florida Herpetological Society and the Santa Fe Community College Endowment Corporation Board of Directors have established a major scholarship program in the Biological Parks Training Program at Santa Fe Community College. The purpose of this scholarship program is to assist selected students in the pursuit of an Associate of Science degree in Biological Parks Management Technology. The Santa Fe Community College Endowment Corporation is the recipient and administrator of this scholarship program established by the Central Florida Herpetological Society.

Students interested in enrolling in the Biological Parks Management Program and who demonstrate an interest in herpetology are encouraged to apply. Students must have good grades, an interest in zoo training, and some degree of financial need. The scholarship consists of $800 for one school year, covering tuition and books.

Additional information may be obtained by contacting: Central Florida Herpetological Society, P.O. Box 3277, Winter Haven, FL 33881, USA. The deadline for scholarship applications is 15 April of each year. ●

REGIONAL HERPETOLOGICAL PUBLICATIONS HAVE PERMANENT HOME

It is common knowledge that interesting and valuable herpetological information is printed in the numerous regional society newsletters. The herpetological community has a centralized location where regional works are housed and where copies of particular articles can be secured. Ms. Nina J. Root, librarian at the American Museum of Natural History, gladly receives all past, present and future newsletters, bulletins, and other publications from regional societies throughout the world.

The library at AMNH catalogues all materials into their permanent collection and provides photocopies of articles at a nominal fee upon request. It is vitally important that all regional herpetological societies furnish the

World Congress of Herpetology

NOMINATIONS SOLICITED FOR NEW OFFICERS AND MEETING SITE

Pursuant to the WCH Constitution *pro tem*, nominations of persons are hereby solicited for election to the Executive Committee (EC) and International Herpetological Committee (IHC) of WCH, as well as proposals for the venue of the Second Congress. All persons are eligible to nominate.

EC. Nominations to the EC must be seconded by any two present members of the EC or IHC (list printed in the Registration Circular available from the Secretariat, WCH, Ecology Research Group, Rutherford College, University of Kent, Canterbury, Kent CT2 7NY, UK; or Telex 965449 UKCLIB G).

IHC. Nominations to the IHC must be seconded by any two present members of the EC or IHC or by the governing body of an Affiliated Organization (list also printed in Registration Circular). In addition, the governing bodies of Affiliated Organizations may nominate to the IHC.

Venue. Individuals or groups who wish to propose sites for the Second Congress (to be held 1992 to 1994) should submit one-page-maximum proposals indicating meeting and housing facilities, names of persons who might serve on local Organizing Committee, and special attractions of the site.

Deadlines. All seconded nominations and venue proposals should be submitted to the Secretary-General: Professor Kraig Adler, Cornell University, Seeley G. Mudd Hall, Ithaca, New York 14853, USA; or Telex WUI 6713054). *Nominations must be received by 1 June 1989*; venue proposals should be received no later than 1 September 1989 so they can be copied for distribution and voting at the Canterbury Congress.

museum with *complete* volumes of past publications and that the museum library be permenently placed on their mailing lists. The address is:

Central Park West at 79th Street
New York, NY 10024 USA

FEATURES

HERPETOLOGY IN SOUTH CHINA

In the not distant past South China provided a broad and continuous corridor between equatorial rain forests and temperate and boreal forests. This forest corridor led not only to the heart of Eurasia, but also directly to the Bering Land Bridge. Today that forest is reduced to scattered fragments and relicts, usually in remote areas and rugged terrain. The process of biogeographic reconstruction is now not unlike a paleontological effort.

From about 1936 to 1976 there was little opportunity for herpetological study of this biogeographically critical region. Notable exceptions include Liu et al. (1960, 1973) and Liu and Hu (1975).

During the last decade there has been a rejuvenation of herpetological activity in South China. The purpose of this report is to review important published works, either new or not readily accessible to westerners, and note new locality records and work in progress.

The most important work to date is Karsen, Lau, and Bogadek (1986): Hong Kong Amphibians and Reptiles. The territory includes Hong Kong island itself (ca. 81 km^2), much larger Lantau (ca. 138 km^2), about 100 other islands and rocks, and more than 700 km^2 of the South China mainland, totalling ca. 1013 km^2. Most of the original forest of the area was gone by the time Europeans saw the territory, but patches of *fung shui* woods remained and formed nuclei for the regeneration of the extensive forests which exist today (La Touche 1934; Viney and Phillipps 1983).

Karsen et al. (1986) provide the most useful and up-to-date work on the herpetology of tropical China available today. Each of the 99 species is illustrated, usually with a color photograph of a living specimen (drawings must suffice for some rarities not seen in the last few years). Each species account includes a general description, remarks on distribution and abundance, economic and medical comments where appropriate (e.g. edible frogs and turtles, venomous snakes), and all the authors know about life history, ecology, and reproduction. These last comments are especially useful because the authors are astute naturalists and maintained a large captive collection. I found in this work data on breeding seasons, clutch sizes, and diet I have never read elsewhere.

The flaws are minor. Tighter species diagnoses would have permitted more certain identifications. These were originally included, but were stricken by the publisher as detracting from the popular appeal of the book. The more complete version would have allowed one to fully resolve all specimens in such look-alike genera as *Opisthotropis* and *Enhydris* (Colubridae).

The work is dedicated to the late J.D. Romer, economic entomologist, whose hobby and passion was herpetology. Romer's works on the Hong Kong herpetofauna (keys and brief guides) are cited. The dependence of Karsen, Lau, and Bogadek on Romer's work leads to a second category of flaws or minor problems: identification and taxonomy. Romer accepted some taxonomic changes uncritically, and was unaware of others; his names persist. The most obvious cases involve the genus *Natrix sensu lato.*

Karsen, Lau, and Bogadek did not include the gecko *Hemidactylus frenatus* in the Hong Kong fauna, although it was recorded there by Smith (1935). Bogadek has since confirmed the presence of a population in Victoria (MCZ Z-36169).

Matsui (1986) examined specimens of *Bufo gargarizans* putatively taken in Hong Kong and stored at the U.S. National Museum of Natural History (USNM). This species was not known to Romer or Karsen, Lau, and Bogadek. I do not believe it occurs in Hong Kong. R. Crombie, USNM, reports (*in litt.*) that these specimens of *Bufo gargarizans* were received from Smithsonian "attache" Pierre Louis Jouy in the early 1880s. One, USNM 37510, was variously logged as "Japan" and "China, Hong Kong?" The others, USNM 46486-95, are associated with specimens of other species of dubious Hong Kong provenance. Crombie suggests Hong Kong was merely the shipping port, and I agree.

In this connection, a second major work deserves comment and review: Pan, Liu, and Qian (1985), a broad-brush review of the amphibians of Guangdong Province. Pan et al. include *Bufo gargarizans* in Guangdong only from north of the divide in the Nanlingshan (mountains of the border region with Hunan Province), to elevations exceeding 700 m. Pan, Liu, and Qian partition the Province two ways: terrestrially and aquatically—in terms of drainage. Their terrestrial zones are mapped. Roughly, the first is the northern, north of the Tropic of Cancer. The second is an inland, eastern region; the third an inland, western region. By far the largest zone is the south coast, including Hainan Dao and all other coastal islands, and the North Pearl River (Bei Jiang) valley to nearly the Tropic. All of this zone is within the tropics *sensu stricto.*

The drainage zones of Pan, Liu, and Qian are also four, but in two major groups. Group

Figure 1. South China, showing localities mentioned in the text: hatching = Hengduanshan and the Dianxi Plateau; star = Huaping forest; and solid dot (with arrow) = Dinghushan.

one, containing no subdivisions, is the drainage north out of the Nanlingshan to (eventually) the Chang Jiang (Yangtze River). This drainage contains three species not found elsewhere in the Province by these authors: *Bufo gargarizans* already noted, the giant salamander *Andrias davidianus*, and the edible frog *Rana nigromaculata*. This last species is of interest because Karsen, Lau, and Bogadek (1986) have recorded it in the wild in the New Territories of Hong Kong in 1966 and 1981. They suggest these individuals represent escaped market imports.

Group two, the remaining three drainage zones, are all part of the Eastern Oceanic Drainage. The first of these, the South, includes drainages to the sea south and west of the west branch of the Pearl—the Xi Jiang—and the Xi Jiang itself. The second, called Central, includes the north branch of the Pearl, the Bei Jiang, and all drainages east of it. A nebulous third zone combines South and Central components. It is not clear from their paper why this exists, but it may reflect human-altered drainage patterns in the recent past.

Pan, Liu, and Qian list 41 species of amphibians in Guangdong Province. Six constitute major range extensions. The salamander *Pachytriton labiatum* was found in the northern zone; this range was included in the major work on Caudata by Zhao and Hu (1984). The whiskered frog, *Vibrissophora yaoshanensis*, was taken in the equivocal, combined South and Central drainage of the northern zone at 750 m. *Rhacophorus mutus* was found from 100 to 300 m in the southern drainage of the southern and western zones. The burrowing frog *Kaloula pulchra hainana* is shown to occur in extreme southern mainland Guangdong; the nominate form occurs throughout most of the rest of the Province.

Two frogs round out the list of new records from Pan, Liu, and Qian. *Rana versabilis* is added from both northern and western zones, in the combined South-Central drainage, at 400-500 m. *Rana latouchii* was found in the Central drainage of the northern region at 500-1200 m. While this may be a new record for Guangdong *sensu stricto*, *R. latouchii* was found in February 1984, breeding in stream pools at ca. 150 m in forest near Tai Po, New Territories of Hong Kong (Karsen, Lau, and Bogadek, 1986). It is most unlikely that this small species, not normally utilized for food, could have been introduced to this natural area by human agency. There are fresh specimens: Museum of Comparative Zoology (MCZ) 108687-8.

Pan et al. did not visit Hainan Dao. Their list leaves out 18 amphibians recorded from that large island by Liu et al. (1973), in a total list of 37 species. Omitting *Kaloula pulchra hainana* which Pan et al. found on the southern mainland, Hainan Dao has at least ten endemic species. Not endemic, *Rana tiannensis* has been added to the list for Hainan Dao, and thus Guangdong Province, by Li, Qian, and Wu (1986).

Two frogs, *Philautus romeri* and *Amolops hongkongensis*, beautifully depicted and well described in Karsen, Lau, and Bogadek (1986) remain known only from Hong Kong and have yet to be collected in Guangdong Province *sensu stricto*.

Thus, there are at least 62 species of amphibians in Guangdong *sensu lato* (including Hainan Dao and Hong Kong).

Another important paper on Guangdong amphibians is provided by Su (1985) on feeding habits. The bulk of the paper details the stomach contents of the common paddy frog, *Rana limnocharis*, and consists primarily of tables listing insects and other arthropods. Thirty other species are also listed on the basis of stomach content analysis, including the enigmatic *Rana nigromaculata*, noted above. Su (1985) notes no geographic provenance for the Guangdong specimens, but found 100 percent Orthoptera as the contents of five stomachs. Because crickets (Orthoptera) are the standard food given *Rana* held captive for eventual human consumption, Su's data contribute to our suspicion that most Guangdong *R. nigromaculata* are imported. Su ranks the six most economically important amphibians as being *Rana tigrina, R. limnocharis, R. spinosa, R. guentheri, R. nigromaculata*, and *Bufo melanostictus*.

Perhaps the best studied region in South China lies some distance from Guangdong and Hong Kong. This is Hengduanshan (Hengduan Mountains) of Yunnan. Yang, Su, and Li (1983) provide the fundamental biogeographic paper on this region. It lies between 24° and 29° N, and 98° and 100° E, just north of the Tropic of Cancer. Elevations vary from about 450 to 3,850 m for the area studied by Yang et al., which includes the Dianxi Plateau and its southward decline. Within this area the authors record a total of 138 species. Yang and Su (1984) subsequently log 139 by adding a new flying frog, *Rhacophorus gongshanensis*.

In a study concentrating on amphibians of high altitudes (especially those ranging over 3,000 m) and primitive forms (especially in the genera *Batrachuperus, Andrias, Tylototriton, Bombina, Megophrys*, and *Oreolalax*), Hu, Jiang, and Zhao (1985) add at least 24 more species. Most recently (I will not say finally) Wu and Zhao (1985) add four more species of frogs of the genus *Amolops* in a karyotypic study of biogeographic import. This brings to at least 83 the number of known amphibians in this area. Some species questions remain unresolved and Li, Yang, and Su (1984) did not do high altitude (over 3,000 m) work, but on present evidence Hengduanshan supports the greatest amphibian diversity in China.

A forest remnant on the Guangxi side of the Nanlingshan, at Huaping, just north of the Tropic (25° 31' - 25° 39') was studied by Wen, Li, and Xu (1984). They note that the area is cool and moist, with mean temperatures varying from 12° -14° C, annual rainfall 2000-2200 mm, and average humidity 80 percent. They found 76 species (Table 1).

My own work has been concentrated at Dinghushan, Guangdong, well south of the Tropic, ca. 80 km west of Guangzhou (Canton): Lazell and Liao (1986). This area is small, ca. 1,200 ha, but rugged, rising to just over 1,000 m. In our list *"Leiolopisma" reevesi* should be *Scincella modesta* (*S. reevesi* occurs at Dinghushan too: Zhou et al. 1981). Perhaps our most signal failure at Dinghushan has been with salamanders. Zhao and Hu (1984) have summarized knowledge of Chinese salamanders and record seven from Guangdong Province: *Andrias davidianus, Pachytriton brevipes, P. labiatum, Tylototriton asperrinus, Paramesotriton chinensis, P. hongkongensis*, and *Cynops orphicus*. Of these, *Andrias* and both *Pachytriton* are unlikely for coastal zone and southern drainage, but any of the others, or species as yet unknown, might well occur at Dinghushan. Certainly *Paramesotriton hongkongensis* is the most obvious candidate.

A number of new locality records may be appropriately listed here. Common names in English are from Karsen, Lau, and Bogadek (who also provide Chinese names). Collection abbreviations are Guangdong Institute of Entomology, Guangzhou (GIE) and Museum of Comparative Zoology, Harvard University (MCZ).

Megophrys brachykolos (Short-legged toad). Hong Kong: Lantau (Lan Island): Keung Shan Tunnel. S. Karsen and J. Lazell coll. 11 March 1987. Michael Lau Wai Neng det. MCZ 109077.

Philautus romeri (Romer's tree frog). Hong Kong: Lantau (Lan Island): Keung Shan Tunnel. Fung Chi-fai and A. Bogadek coll. 13 April 1986. A. Bogadek and J. Lazell det. MCZ 108700. First record off Lamma Island.

Lygosoma indicum (Brown forest skink). Guangdong: Dinghushan, 50-220m. S. Eagle and A. Cleveland coll., 23-25 May, 1986. J. Lazell det. GIE 30305-7, 30309.

Pareas margaritophorus (White-spotted slug snake). Guangdong: Dinghushan, 70-185 m. K. Richardson and C. Henderson coll., 10 May and 27 May, 1986. J. Lazell det. GIE 30292 and 30319.

Achalinus rufescens (Rufous burrowing snake). Guangdong: Dinghushan, ca. 320 m. N. Goodyear coll., 26 May, 1986. J. Lazell det. GIE 30312.

Natrix percarinata (Mountain water snake). Guangdong, Dinghushan, 125-200 m. J.

Table 1. Areas and known species numbers in South China. Sources of data are varied and cited in the text. New records noted in the text are included, but a refuted record (*Bufo gargarizans*, Hong Kong) is not.

	Area, km²	Elevation, m	Amphibians	Reptiles
Dinghushan	12	20-1,000	14	37
Huaping	139	500-1,600	26	50
Hong Kong[1]	1,013	0-958	22	78
Hengduanshan	85,500	450-4,950	83	84
South Yunnan	126,000	100-2,850	77	--
Guangdong	210,000	0-1,500	62	--

[1]Hong Kong includes not just the island of that name but ca. 100 other islands and ca. 700 km² of mainland.

Lazell and K. Richardson coll., 11 May, 1983 and 7 May, 1986. J. Lazell det. MCZ 166906 and GIE 30289.

Boiga multimaculata (Many-spotted catsnake). Guangdong: Dinghushan, 220 m. S. Karsen and N. Goodyear coll. 14 April 1987. S. Karsen det. MCZ 172042.

Micrurus macclellandi (MacClelland's coral snake). Guangdong, Dinghushan, ca. 240 m. N. Goodyear coll., 26 May, 1986. J. Lazell det. GIE 30310. *Micrurus* is preferred over *"Calliophis"* as a generic name based on McDowell (1986).

Natrix sauteri (Sauter's keelback). Hong Kong: New Territories: Shek Kong. Fung Chi-fai coll., September, 1985. A. Bogadek and J. Lazell det. MCZ 171462.

There is a tremendous amount of herpetological work to be done in China. The rewards are truly impressive. As previously stated (Lazell and Liao 1986): "We believe we have only begun our compilation. . ."

I am especially indebted to Liao Wei-ping, Zhao Ermi, and Hu Shu-chin for their help and hospitality in China, and to Fr. Anthony Bogadek in Hong Kong. My work has been supported by The Conservation Agency and Earthwatch, the Center for Field Research. Both have provided many colleagues and able assistants in the field. Jose Rosado and Franklin Ross curated considerable fresh material now at MCZ.

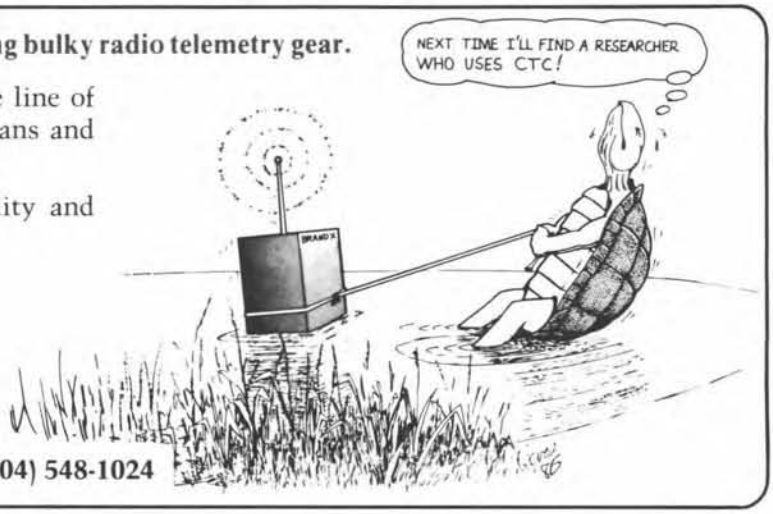
WESTERN SPOTTED FROG *(Rana pretiosa)* MORTALITY FOLLOWING FOREST SPRAYING OF DDT

In June and July of 1974, 172,695 hectares of forest in Oregon, Washington, and Idaho were sprayed with 1,1,1-trichloro-2,2-bis-(p-chlorophenyl) ethane (DDT) for control of the Douglas fir tussock moth, *Orgyia pseudotsugata* (Graham et al. 1975). State and federal agencies undertook an extensive environmental monitoring program in connection with the DDT application (U.S. Department of Agriculture 1981). That program included no planned monitoring of amphibians. I made routine observations of western spotted frogs, *Rana pretiosa,* prior to the DDT application, and discovered dead frogs after the DDT application. The decision to sample frogs was not made until the dead frogs had been discovered. The requirements of the planned monitoring severely limited the field and laboratory resources that could be devoted to studying frogs.

METHODS

On 28 May 1974, I heard and saw *R. pretiosa* at a 0.05 ha pond behind a man-made dam on Mill Creek at 45°32'53" N latitude, 118°22'32" W longitude, Umatilla County, Oregon. On 12 June 1974, I captured and released 14 of those frogs.

The vicinity of the pond was sprayed on 25-26 June 1974 with DDT in auxiliary solvent and fuel oil at a nominal rate of 0.72 kg DDT/ha, and a nearby area was sprayed on 26-27 June 1974 at a nominal rate of 0.65 kg DDT/ha (Graham et al. 1975).



On 20 July 1974 I collected 20 dead frogs (all that I found) and six live frogs (not all that I saw) from the pond. The dead frogs were on the bottom, concentrated in and around a small "spring box" near the pond inlet. The

No species of study should be burdened with carrying bulky radio telemetry gear.

Custom Telemetry & Consulting offers a complete line of external and implantable transmitters for amphibians and reptiles with a wide range of options.

dead frogs were intact, but showed some "bloating" from decomposition. I put the live frogs in three acetone-washed metal cans in pairs and the dead frogs in three acetone-washed cans in groups of six, seven, and seven, and froze them on dry ice in the field. The frogs were kept frozen during shipment to the laboratory.

The Oregon Department of Agriculture Laboratory Services used a modified Mills, Onley, Gaither procedure (Anon. 1972) to measure DDT and DDT analog residues in 25-gram samples from each can (17.5 g from one can). The analytical chemist drew the samples from each can by taking enough frog tissue to give the desired weight. Not all frogs in each can were tested.

On 8, 9, and 10 June 1976, I walked around the pond and counted 10, 6, and 10 live *R. pretiosa*, respectively. I visited the pond on a number of occasions before and after the DDT application; the only time I found dead frogs was on the first visit after the DDT application.

RESULTS

The results of the DDT residue analyses appear in Table 1. The sample sizes are too small and the sampling scheme was too haphazard to warrant the assumptions necessary for meaningful statistical analysis.

DISCUSSION

Laboratory studies (Ellis et al. 1944; Logier 1949; Boyd et al. 1963; Ferguson and Gilbert 1967; Sanders 1970; Tucker and Crabtree 1970) establish that DDT is toxic to frogs, but are not otherwise helpful in evaluating the data reported here because none relates DDT tissue residue levels in frogs to DDT mortality.

The application rate of DDT that preceded the frog mortality I observed was lower than that associated with frog mortality observed by others in the field (Lackey and Steinle 1945; Tiller and Cory 1947; Logier 1949; Fashingbauer 1957).

The frogs I collected presumably had background levels of DDT in their tissues prior to the DDT application. All of the species (fish, birds, and mammals) for which prespray residue data were collected in the course of the monitoring program showed prespray "background" levels of DDT in their tissues (U.S. Department of Agriculture 1981). Cory et al. (1970) found background levels of DDT in frogs from remote areas of the California Sierra Nevada that had never been treated with DDT. Kuhr (1974) found DDT residues in frogs from a stream near an orchard that had not been treated with DDT for 12 years.

The residue levels reported here probably were above prespray background levels, although the absence of prespray residue data precludes knowing that with certainty. Every species monitored as part of the planned monitoring program showed substantial increases in residue levels following the DDT application (U.S. Department of Agriculture 1981). Meeks (1968) found a similar increase in *Rana pipiens* after an experimental application of DDT.

Conclusions based upon comparison of DDT levels between the live and dead frogs must be drawn with caution. In addition to the uncertainty due to the small sample sizes and the haphazard sampling scheme, the situation is further confused by possible postmortem changes in tissue density, by the unknown effect of death upon the movement of DDT and its analogs into or out of a frog's body, and by the possible contribution to residues by contaminated food in a frog's gut. The relatively higher levels of DDD in dead frogs may be the result of postmortem microbial conversion of DDT to DDD (Spencer 1967) and should not be assigned any toxicological significance without further investigation.

Notwithstanding the uncertainty regarding the residue data, the data and observations reported here constitute circumstantial evidence suggesting that application of DDT at a nominal rate of 0.7 kg/ha caused some mortality in *Rana pretiosa*.

R. pretiosa is protected in Oregon by administrative rules of the Oregon Fish and Wildlife Commission. It may be absent from its former range in western Oregon and Washington and has a spotty distribution in the Cascade Mountains (Nussbaum et al. 1983; Storm 1986). Given that status and the observations reported here, *R. pretiosa* should be presumed for decision-making purposes to be sensitive to DDT, and possibly to other insecticides, when chemical pest control is being contemplated near *R. pretiosa* habitat.

Table 1. Residues (parts per million) of DDT and its analogs in western spotted frogs, *Rana pretiosa*, approximately three weeks after DDT application.

ACKNOWLEDGMENTS

My observations were made while I was engaged in monitoring DDT residues in small mammals as an employee of the Oregon State Department of Human Resources Health Division. The Health Division conducted that monitoring with financial assistance under Environmental Protection Agency contracts 68-02-0708 and 68-01-3130. Residue analyses were performed by the Oregon State Department of Agriculture Laboratory Services with financial assistance from the U.S. Department of Agriculture Forest Service. Brent Frazier assisted in the field. Dr. Michael Wehr read and commented on an early draft of the manuscript.

Ambystoma tigrinum LOCALITY RECORDS—BE WARY

The tiger salamander, *Ambystoma tigrinum,* has a puzzling distribution in Louisiana and Mississippi. There is a huge hiatus in the continuity of the species from central Alabama to Texas, from what can be determined as valid records. Old records from Mississippi are ambiguous or questionable, but Boyd and Vickers (1963) reported specimens collected at Starkville, Oktibbeha County, that were deposited at the Mississippi State University Museum. I commented on the distribution of the species in Louisiana (Dundee 1974), citing modern records for extreme western Louisiana in Vernon and Beauregard parishes, and adding a new record for extreme southeastern Louisiana (St. Tammany Parish). The latter locality has subsequently been extremely modified by commercial tree farms. Cope (1889) mentioned two specimens from Grand Coteau, St. Landry Parish (USNM 4706), giving details for one that he said was an immature stage. Neither I in 1973, nor Percy Viosca at an earlier time, could find these specimens at the National Museum of Natural History. At least one earlier worker (Beyer 1900) maintained (without listing voucher specimens) that *Ambystoma tigrinum* was common in Louisiana and occupied much of the same range as *A. punctatum (= A. maculatum),* a species he claimed was one of the most common in the state.

On a recent visit to the Northeast Louisiana State University Museum of Zoology I examined tiger salamanders collected in May 1978 just north of Rayne, Acadia Parish, Louisiana. This surprising record seemed to confirm that the USNM St. Landry Parish record probably was indeed valid. The locale obviously was worth visiting to learn more about the biology of this poorly known Louisiana salamander species.

A remarkable detective story now emerges, with a surprise ending. The collection-site data did not quite tally with the actual road directions and distances. After querying several local residents as to whether they had ever seen tiger salamanders or where there might be a pond (rice paddies were the only pooled water observable) I discovered that one of the local residents, Mr. Sidney Arceneaux, had undertaken a commercial venture raising salamanders. He had obtained breeding stock from a person in Tulsa, Oklahoma, who was promoting aquaculture of tiger salamanders for fish bait. The Acadia Parish stock had allegedly come from a site in Oklahoma near the Missouri border (I am not aware of any records for that region of Oklahoma—the species is uncommon in nearby sections of Kansas, Missouri, and Arkansas). The salamanders, fed a commercially prepared food, reproduced well in a 30-acre impoundment for about four years until heavy rains washed out the operation, which has since been abandoned.

With the advent of such commercial enterprises as that described above we may expect more introductions of tiger salamanders into areas outside their natural range, and we may begin to find specimens unrepresentative of the race endemic to that region. Although herpetologists may object to such introductions, in all likelihood the practice will continue with the blessings of many state wildlife and fisheries departments, especially if they see potential economic benefits.

OBSERVATIONS ON THE FEEDING HABITS OF *Ameiva ameiva*

Little is known of the ecology of lizards from Argentina. In spite of information on the trophic biology of semidesert lizard communities (Sage 1974) and on general aspects of the diet of some species (Gallardo 1977; di Tada 1982) very little is known about their feeding ecology.

The objective of this study was to determine the trophic spectrum for the terrestrial teiid lizard *Ameiva ameiva* from the Chaco forest community. This lizard's distribution extends from Panama to northern Argentina, east of the Andean Mountains (Vanzolini et al. 1980). We provide information on diet composition and on the trophic position of the species within the Chaco forest lizard community.

The area of study fits into the Occidental Chaco District of the Chaco Province, with dry weather and xerophilous, deciduous forest with a herbaceous gramineous stratum as the dominant vegetation (Cabrera and Willink 1973). The sample, made up of 40 specimens of *Ameiva ameiva* was collected with firearms (Chani 1980) from December 1959 to October 1972 in two departments N.E. of Tucuman Province and in one department N. of Salta Province in the Occidental Chaco Subregion. Capture areas were demarcated within the scarce original natural forest remains, relatively unaltered by human activity.

Analyses of stomach contents were made for each specimen. Prey was classified to the level of order or family in addition to life history stages (larvae, chrysalis, adults). For each food type, number, volume and frequency were calculated (Pianka 1971); absolute frequencies were the total number of lizards that contained at least one specimen of a particular item in their stomachs, and relative frequencies were based on the total number of lizards in the sample.

Table 1 lists the observed organisms: Twelve taxonomic groups in addition to cocoons, eggs and vegetative remains. Ninety-five percent of the total diet volume consisted of animal matter and only five percent was plant matter. Sixty percent of the latter were fruits and the remaining 40% were vegetative, and to a lesser extent floral, remains.

Isoptera were the most important prey numerically (60%), but relatively unimportant volumetrically (6%). Adult coleopterans were significant prey in volume as well as in number, followed by spiders, and lepidopteran and coleopteran larvae. Of the less-represented items, Gryllidae, Blataria and chrysalis stand out in numbers. Ants were only important numerically. The high deviation values with regard to the numerical and volumetric means of the various categories could reveal different individual selective lizard response to the same item, or the preys' distribution type in the environment.

Relative frequencies of the prey categories provide insight into the general foraging patterns of the lizards; adult coleopterans (80%), spiders (66%), isopterans (50%), lepidopteran larvae and plant remains, were most important in this respect.

Foraging mode is related to the type of prey eaten by lizards (Huey and Pianka 1981): the

higher frequency of prey of relatively difficult access, such as isopterans, spiders and larvae, suggests a wide foraging strategy as a means of obtaining food. This appears to be a common feature of teiid lizards (Pianka 1970, 1973; Vanzolini 1980).

From the foregoing analysis, *Ameiva ameiva* is a generalist predator that preys on small and medium size arthropods, as well as plant material (leaves, stems, flowers and fruits). Arthropod prey consists mainly of insects and arachnids, including primarily Coleoptera (adults and larvae), Araneida, Isoptera and Lepidoptera (larvae). Because of their high number, volume and frequency they constitute the basic food of *Ameiva ameiva* diet. In contrast, the other food items were of very low frequency, suggesting they are occasional or complementary food.

CLEANING OF THE HAWKSBILL TURTLE *(Eretmochelys imbricata)* BY ADULT FRENCH ANGELFISH *(Pomacanthus paru).*

Cleaning symbiosis between various aquatic organisms has been widely referenced in both scientific and lay literature for over three decades. Most reports involve interspecific interactions between marine fishes, with fewer descriptions involving fish and crustaceans. Although marine turtles in general, and the hawksbill *(Eretmochelys imbricata)* in particular, are known to carry a diverse variety of ectoparasites or commensals (Frazier et al. 1985, Hubbs 1977, Ernst and Barbour 1972, Carr et al. 1966 and others), I am aware of only one brief report of the cleaning of a marine turtle in the wild (Booth and Peters 1972). That interaction occurred off Australia, involved green turtles *(Chelonia mydas)* with two species of fish, moon wrasses *(Thalassoma lunare)* and damselfish *(Abudefduf sexfasciatus).*

The following discussion describes a cleaning interaction between a hawksbill *(Eretmochelys imbricata)* and two French angelfish *(Pomacanthus paru).* It should be noted that juvenile angelfishes are widely reported to occasionally clean other fishes (Boschung et al. 1983, Randall 1968, Marshall 1966). Limbaugh (1962) reported adult French angelfish being cleaned by the neon goby *(Elecantinus oceanops).* However, there are no reports of adult French angelfish acting as cleaners or of hawksbills being cleaned by other organisms.

The interaction occurred on 13 November 1985 in 22 m of water off the southwest tip of Grand Cayman Island, B.W.I. The location is atypical of most of Cayman's reefs; it consists of a flat rock bottom with a thin veneer of sand and low relief (1 m) coral spurs and large numbers of gorgonians. For two minutes, observations were made (from a distance of 3 m) of two French angelfish in proximity to a hawksbill turtle, then from 1 m for an additional minute. When I moved closer than 0.6 m, the turtle suddenly swam off. The French angelfish remained in the area 15 min, but the turtle was not seen again.

While being cleaned the hawksbill, tentatively judged to be a female between 75-85 cm total length (TL) with an estimated carapace length of 55-65 cm, was positioned on the sand. The front flippers were extended downward and to the side at approximately 60° to the long axis of the carapace; the rear flippers were extended nearly straight back with a gap between their inner margins. Front flipper placement resulted in the hawksbill being propped, head up, off the sand at an angle of about 45°.

Two large adult French angelfish (ca. 40 cm TL) were actively swimming over the hawksbill and biting at it. The two fish nibbled simultaneously at the right and left front flippers, respectively. Independently the fish would turn on their sides and swim under the anterior portion of the plastron and push their mouths into the pectoral axillae. Hubbs (1977) noted the presence of pelagic crabs *(Planes cyaneus)* in the pectoral axillae of a Pacific ridley *(Lepidochelys olivacea)* off California. No ectoparasites, lesions or abnormalities of any kind could be seen in the axilla or any place else on the hawksbill, with the exception of a thin film of algae on the lateral margins of the posterior half of the carapace.

The French angelfish moved up and down over the front flippers, under the plastron and around the turtle's mouth. Unlike many fishes who are cleaned, the turtle did not jerk, twitch or open its mouth. In fact, the hawksbill remained perfectly still and did not turn or stretch, in apparent accommodation to the cleaners, as discussed by Booth and Peters (1972) for the green turtle. Of course the elevation of the carapace by extension of the front limbs may have enhanced exposure to the cleaner fish.

Frazier (1985) shows that cheloniid turtles are suitable substrates for mollusks and other organisms and comments that the rareness of turtle epizoa needs explaining. Despite the paucity of observations regarding the cleaning of sea turtles it seems possible that these creatures often utilize the services of cleaner fish to rid themselves of ectoparasites. It seems less likely that adult French angelfish regularly clean hawksbills, or any other sea turtles, because although these species are regularly sighted in the same areas cleaning behaviour has never been reported.

THREE GENERATIONS OF CAPTIVE-HATCHED DESERT TORTOISES, *Xerobates agassizii*

There are few records of achieving an F2 generation among chelonians (Coakley & Klemens 1983; Kirsche 1985). The hatching of three desert tortoises in September 1985 marks the first documented F3 generation among terrestrial chelonians.

An adult male and female *Xerobates (Gopherus) agassizii* came into the senior author's possession in 1935. Precise geographical origin is uncertain but was probably central San Bernardino County, California. Nesting by the female was first observed 27-29 June 1956. The subsequent hatching in September of two eggs incubated artificially was heralded at the time as a first in chelonian husbandry (Booth 1958). While two other artificially incubated eggs failed to hatch, three others removed from the nest in early September hatched by 19 September. In November 1956, the remaining eggs in the nest were found to have spoiled. The two original F1 tortoises are still alive, as are the parent tortoises, which continue to produce offspring yearly or twice yearly until the present day.

INCUBATION TECHNIQUE

Eggs removed from outdoor nests are placed in a plastic bowl filled with one cm of washed sand. Indentations are made for each egg; after these are placed in the sand the bowl is covered with a damp cloth. Heat is provided with a 40 watt incandescent bulb suspended over the bowl. The temperature of the sand surface is kept at 26-27° C. Every few days the cloth cover is dampened.

Once actual hatching begins, the egg is removed to a sheet of waxed paper to prevent sand from adhering to the yolk sac. The gestation period under such conditions has varied from ninety to one-hundred fifteen days.

Hatchlings sometimes have appeared in August through October from undetected nests. The gestation period for such nests is not known.

RESULTS

Tables 1-3 summarize the reproductive output of artificially incubated eggs produced by F1 and F2 tortoises. Data are lacking for 1972 as neither nesting nor hatchlings were observed, and for 1984 because eggs from both generations were incubated together. Records were not suitably kept between 1978 and 1982. The reproductive failure in 1986 can be attributed to an electrical failure; the single 1986 hatchling emerged from an undetected nest. Three hatchlings from unde-

F2	32	8	7-8

tected F2 nests appeared in 1976. Among the total of eight hatchlings produced that year were four xanthic tortoises. The first clutch of F2 eggs (1983) failed to hatch and was apparently infertile.

It is estimated that about 60% of eggs left in the ground eventually hatch. Many young tortoises produced by either incubation method have been placed in other people's possession, and there is no way to document their reproductive accomplishments.

In addition to the xanthic young previously mentioned, several F2 tortoises with mandibular malocclusion (possibly related to a deformed hyoid bone) have appeared. Inbreeding is certainly responsible for this problem. Knoll formation of the carapace is more marked in the F1 generation than in the succeeding tortoises, and may be related to the relative lack of essential nutrients in the F1 juvenile diet. Supernumerary scutes have appeared in some hatchlings.

DIET

Food for three generations of captive-bred desert tortoises has consisted of garden produce (especially iceberg lettuce) and grass. Since 1976, they have been given chick starter and ground oyster shell as supplements.

HUSBANDRY

Tortoises are kept outside most of the year, segregated by size in enclosures. Hibernation is accomplished by taking the animals indoors for closer supervision in an ambient temperature of 10-15° C. Tortoises under the age of two years are not allowed to hibernate fully, nor are tortoises younger than four or five years left outside overnight. Occasionally post-hatchling tortoises show a strong inclination to hibernate but are not permitted to remain dormant longer than two weeks.

THE REPRODUCTION OF *Natrix tessellata* IN ISRAEL

The diced water snake *Natrix tessellata* is common in the central and northern parts of Israel, especially near water sources such as streams and fish ponds. Although fish are a major part of its diet this snake is too small to eat large carp and cyclids, the chief types of fish kept in fish ponds in Israel. Claims of it causing significant damage are, therefore, erroneous. An alarming reduction in numbers has recently been noted for this species (Werner 1988), perhaps in part as a result of deliberate mass killings by fish growers.

Although it is commonly kept as a pet, little has been published about its reproduction.

While doing research on the physiology of reptile eggs, a considerable body of information concerning the reproduction of this snake has been collected in our laboratory and is summarized in Table 1, together with the little information that has appeared in the literature about its reproduction in Israel.

Much of the information about clutch size was collected in the summers of 1986-87, when we were fortunate enough to receive some 350 specimens from kibbutz HaZorea, where it is considered a major pest in the fisheries. Each year, the 35 largest specimens were retained and housed in four large terrariums, eight to nine specimens per cage, on the assumption that a large proportion of them would be gravid females. Sawdust ca. 4 cm deep) was used to cover the bottom and provide a laying substrate. Water was given freely, in a dish large enough for total immersion of several snakes, and shelter was provided by several broken, hollow bricks. The snakes were fed on green toads (*Bufo viridis*) and dead fish.

In two reproductive seasons (13 July-25 August 1986 and 24 July-29 September 1987) 59 females laid a total of 678 eggs. Mean number of eggs per clutch was 12.3±4.58, and mean egg mass was 7.2±1.42 g. While normal eggs were oval and white, one early clutch (four eggs) and some of the eggs in the largest clutch (eight of 22) were teardrop shaped, yellow in color, half the normal size, and did not hatch.

Eggs were incubated on wet sand (5% to 20% water content), at 30°±1.5° C. Air humidity was kept at a high level by putting a water dish inside the incubator. Hatching success was over 85% for eggs used as control and in non-destructive experiments. One clutch (12 eggs) was spoiled three days after laying, and another (13 eggs) was attacked by an unidentified nematode.

Due to its docile nature, this species is an

ideal captive. Establishment of captive breeding colonies should be easy, and could solve some of the conservation problems caused by uncontrolled killing by fishermen, on one hand, and by overcollecting by reptile enthusiasts, on the other.

TECHNIQUES

VOLUNTARY INGESTION OF RADIOTRANSMITTERS BY SNAKES IN THE FIELD

Most radiotelemetric studies of snakes in the field have used either surgically-inserted or force-fed transmitters (e.g. Parker and Brown 1972; Madsen 1984; Reinert 1984). One major disadvantage of both techniques has been disturbance to the animal, which may result in modified behavior (e.g. decreased locomotor activity, greater tendency to flee from humans) for some unknown time period following implantation. These problems are exacerbated if study is brief in duration, due to equipment malfunction or limitations of battery-life in the transmitters.

We attempted to overcome these problems in a study of free-ranging blacksnakes (*Pseudechis porphyriacus,* Elapidae) in the Macquarie Marshes of central New South Wales, Australia (Shine 1987). Live white laboratory mice were carried in the field. When a foraging or basking blacksnake was sighted, we killed a mouse by cervical dislocation, disembowelled the mouse and inserted a radio-transmitter (J. Stuart Enterprises, model # TT-IU-160: 55 x 20 mm, 38 g). The abdomen of the mouse was then sutured closed with cotton thread. A 2 m lengthof fine nylon fishing line was passed through a fold of skin near the base of the mouse's tail (using a sewing needle), and a single knot was tied at the end of the line to prevent the mouse from slipping off. The free end of the fishing line was attached to a 4 m fibreglass fishing pole. The entire procedure took less than two minutes.

The mouse was then dragged along the ground ca. 1 m in front of the snake's head, and in most cases was immediately seized (Fig. 1). When the mouse was securely held by the snake, a hard jerk on the fishing line pulled the knot through the mouse's skin, freeing the mouse to be swallowed by the snake. Thirteen snakes were implanted in this way. The only failures of the technique were (1) snakes too small to swallow the transmitter, despite repeated attempts; and (2) snakes frightened by our approach. We also used the technique successfully on an eastern brownsnake, *Pseudonaja textilis,* and on many other blacksnakes (for practice rather than transmitter insertion). Snakes generally took longer to swallow the unit than would have been required to ingest a similarly-sized mouse without the transmitter.

Our success using the voluntary ingestion technique is surprising in view of the open nature of the terrain (we were clearly visible to each snake when offering the mouse), and the unnatural type and presentation of the prey. Mammals constitute only a small proportion of the diet in *P. porphyriacus* (Shine 1977) and have never been recorded in gut contents of Macquarie Marshes specimens (Shine, unpublished data). Success of the technique was probably due to the fact that blacksnakes are voracious feeders: freshly captured specimens have consumed other reptiles while in collecting bags (personal observation), and one blacksnake was seen to eat a desiccated, flattened road-killed frog (D. Wotherspoon, personal communication). We found that blacksnakes ate mouse-transmitter packages larger than we thought possible, and certainly larger than we would have considered force-feeding. On later dissection, one small snake sacrificed at the end of the study showed lesions at the hind end of the stomach, at the point where the transmitter lay against the gut epithelium. These lesions may have resulted from internal physical trauma when the snake tried to crawl through an opening too small to allow passage of the transmitter; on one occasion we saw this animal reverse direction from a crack in a log after the protruding bulge of the transmitter prevented its repeated attempts at forward movement. Whether digested food could pass around the transmitter in these smaller animals is not known. The technique may be applicable to other large snakes and lizards (Christian et al. 1983), and is particularly worth considering for short-term studies where disturbance artifacts may be major problems.

Figure 1. A blacksnake seizing a dead mouse with an implanted radiotransmitter; note open nature of vegetation in study area.

ACKNOWLEDGMENTS

We thank G. Ross for technical assistance, and G. Grigg for encouragement, and loan of telemetry equipment. T. Shine cheerfully selected and carried the mice in the field.

THE COMPLETELY ILLUSTRATED
ATLAS
OF REPTILES AND AMPHIBIANS FOR THE TERRARIUM

Fritz Jürgen Obst **Dr. Klaus Richter** **Dr. Udo Jacob**

Editor, English-language edition: Jerry G. Walls

OVER 2000 PHOTOS — MORE THAN 1500 IN FULL-COLOR

Here is a truly comprehensive and beautiful volume covering all the reptiles and amphibians kept in terrariums plus virtually all the oddballs and rarities any hobbyist (or scientist, for that matter) is likely to ever see or want to know about. Illustrated in full color are hundreds of common and rare reptiles and amphibians, invertebrates, food animals, terrarium plants, environments, and diseases, with hundreds more black and white photos and line drawings. But don't think that this book is just pictures—the authoritative and useful text covers thousands of species, the majority of genera, and hundreds of topics dealing with terrarium care and natural history. The alphabetical arrangement makes it easy to find information on almost any topic you can think of, and you can be sure the information is correct and up-to-date.

The photos represent the work of dozens of photographers in the United States, England, Europe, and South America, brought together to produce the most comprehensive and well-illustrated single volume ever published on terrarium animals. Included is extensive coverage of such popular genera as *Lampropeltis, Elaphe, Anolis, Geochelone,* and *Hyla,* but the true rarities are also well-illustrated, including genera and species most readers will have never encountered before anywhere.

This volume is the perfect answer to the terrarium keeper's dilemma of attempting to find where an animal originated and what type of habitat it requires. It is the obvious first place to look for a solution or a hint to all your questions while having fun looking at the marvelous photos at the same time.

CENTROLENELLA COLYMBIPHYLLUM (Glass Frog). PANAMA: PROVINCIA DE COLON: Distrito de Colón: Parque Nacional Soberania, Pipeline Rd., along the Río Frijoles, 9°09'06" N, 79°43'58" W, elev. 45 m. 16 January 1982. R. Ibáñez, J. R. Ibáñez, T. Jacobs, C. A. Jaramillo and F. E. Jaramillo. Verified by R. Ibáñez, C. A. Jaramillo and F. E. Jaramillo. Círculo Herpetológico de Panamá (CH 0961-0962). Known only from Costa Rica; however, a broader geographic range was suspected for *C. colymbiphyllum* (Starrett and Savage 1973. Bull. So. Calif. Acad. Sci. 72:57-78). New country record, confirms the presence of this species in Panamá and extends the range ca. 363 km (airline) E of Las Cruces, Costa Rica (Starrett and Savage 1973 op. cit.).

Submitted by **CESAR A. JARAMILLO, FIDEL E. JARAMILLO,** Circulo Herpetológico de Panamá, Apdo. 10762, Estafeta Universitaria, Panamá, Rep. de Panamá, and **ROBERTO IBAÑEZ D.,** The University of Connecticut, Box U-43, Storrs, CT 06268, USA ●

CENTROLENELLA PULVERATA (Glass Frog). PANAMA: PROVINCIA DE COLON: Distrito de Colón: Parque Nacional Soberania, Pipeline Rd., approx. 100 m downstream from the bridge on the Rio Frijoles, 9°09'03" N, 79°44'07" W, elev. 45 m. 3 July 1987. R Ibáñez, F. Crastz and L. A. B. de Crastz. Verified by C. A. Jaramillo. Círculo Herpetológico de Panamá (CH 1725). Known in Panamá from three localities only (Starrett and Savage 1973. Bull. So. Calif. Acad. Sci. 72:57-78). New province record, partially fills the gap between previous records.

Submitted by **ROBERTO IBAÑEZ D.,** Circulo Herpetológico de Panamá, Apdo. 10762, Estafeta Universitaria, Panamá, Rep. de Panamá ●

CENTROLENELLA VIREOVITTATA (Glass Frog). PANAMA: PROVINCIA DE PANAMA: Distrito de Capira: Parque Nacional Altos de Campana, along stream undercrossing road to Chicá, 5.7 km from the InterAmerican Highway, 8°41'10" N, 79°54'58" W, elev. 630 m. 25 August 1981. R. Ibáñez, C. A. Jaramillo and F. E. Jaramillo. Verified by R. Ibáñez, C. A. Jaramillo and F. E. Jaramillo. Círculo Herpetológico de Panamá (CH 0649-0651). Known only from three localities in Costa Rica (Starrett and Savage 1973. Bull. So. Calif. Acad. Sci. 72:57-78; Hayes and Krempels 1985. SSAR Herp. Review 16:31). New country record, located ca. 438 km (airline) E of the type locality reported by Starrett and Savage (1973 op. cit.).

Submitted by **FIDEL E. JARAMILLO, CESAR A. JARAMILLO,** Circulo Herpetológico de Panamá, Apdo. 10762. Estafeta Universitaria, Panamá, Rep. de Panamá, and **ROBERTO IBAÑEZ D.,** The University of Connecticut, Box U-43, Storrs, CT 06268, USA ●

HYLA VERSICOLOR (Gray Treefrog). USA: MISSISSIPPI: Warren Co: 13 km SE Vicksburg. 18 May 1987. H. A. Dundee. Verified by H. A. Dundee using cell size measurements and voice recognition. Tulane University (TU 20664). New state record. Extends range 230 km N and NNE of nearest records, which are in Louisiana (Dundee and Rossman, in press. The Amphibians and Reptiles of Louisiana).

Submitted by **HAROLD A. DUNDEE,** Department of Biology, Tulane University, New Orleans, LA 70118, USA ●

RANA TEMPORARIA (Common Frog). GREECE: Mountain Rodope Co: West Rodope, altitude 1350 m, near village Livadites, along Soouk-Sou stream. July 1986. I. Chrysopoulos, N. Eleuftheriades, M. Hatsiioanou. Verified by Th. S. Sofianidou. Aristoteleion University of Thessaloniki, Department of Zoology (AUTDZ 2548). First record for Greece; southernmost locality for the species.

Submitted by **THEODORA S. SOFIANIDOU,** Department of Zoology, Aristoteleion University of Thessaloniki, 54006 Thessaloniki-GREECE ●

PHRYNOHYAS VENULOSA. ARGENTINA: SANTIAGO DEL ESTERO: Copo Department: Monte Quemado (25°48'S, 62°52'W). 20 December 1986. E. Lavilla and G. Scrocchi. Verified by G. Scrocchi and E. Lavilla. Herpetological collection Fundaciõn Miguel Lillo (FML, Amphibians 03707). New Province Record. The specimen and others not collected were found in a dry, chacoan area at the margin of a semipermanent pond. Previously known in Argentina from forested, humid areas of Jujuy, Salta, Formosa, Chaco, Entre Rios and Corrientes Provinces (Cei, J.M. 1980. Monitore Zool. Ital. (N.S.) Monogr. 2:447).

Submitted by **GUSTAVO J. SCROCCHI** and **ESTEBAN LAVILLA,** PRHERP-CONICET, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, República Argentina ●

CAUDATA

AMBYSTOMA MACULATUM (Spotted Salamander). USA: MICHIGAN: Leelanau Co.: North Manitou Island, logging road (45°05'44" N, 85°00'09" W). 3 August 1987. L. B. KATS, R. A. Linton, and M. C. Linton. Computerize Your
Field Notes and Collections

GECKO is a computer program for managing field notes and collections.

GECKO will allow you to:

Record genus, species, subspecies, number, locality, county, state, collector or observer, collection number and comments. Family, order and class are entered automatically.

Extract data for viewing, editing or printing by any combination of the above, e.g. iguanid lizard localities for Inyo Co, CA or all herps seen in Texas from June through August.

List data by order of entry, by date or phylogenetically.

Copy selected records to files for use with spreadsheets, word processors or data base programs.

Count number of species for all or part of the data base, e.g. number of species for 1988 or number of species of *Hyla*.

GECKO is very powerful, yet uses simple screen menus. It incorporates a master species list and is sold with your choice of the U.S. and Canadian list of herps, birds or mammals. Other species lists can be purchased separately and merged into a comprehensive list of terrestrial vertebrates. Lists can be easily edited to accommodate taxonomic changes or new species.

GECKO runs on IBM PCs and compatibles with 320K RAM and DOS 2.0 or later. $75 + $3 shipping. California residents add 6% tax. Please specify species list to be included. Additional lists are $25 each. Similar programs which use common names are available for all terrestrial vertebrates.

Sandpiper Software 153 Michele Circle, Novato, CA 94947

and Jorae 1980. Jack Pine Warbler 58:4-15; Case and Scharf 1985. Jack Pine Warbler 63:17-23).

We would like to thank Max Holden and the staff of Sleeping Bear Dunes National Lakeshore for logistic support during our study.

GERRHONOTUS LIOCEPHALUS INFERNALIS (Texas Alligator Lizard). USA: TEXAS: Brewster Co.: Del Norte Mts., Seale Altuda Ranch, ca. 20.1 km E of Alpine off US Hwy 90. 29 August 1987. J. M. Carignan. Verified by J. F. Scudday. Sul Ross State University (SRSU 5817). Only prior known Brewster Co. population in Chisos Mts., Big Bend National Park (J. F. Scudday, pers. comm.). Extends range ca. 161 km N of Big Bend National Park and verifies hypothetical range connecting specimens from Big Bend National Park with specimens from east of the Pecos River (Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press. 434 pp.)

Submitted by **JEANETTE M. CARIGNAN,** Department of Biology, Sul Ross State University, Alpine, TX 79832, USA

HOMONOTA BORELLII (Neotropical Gecko). ARGENTINA: MENDOZA: Ciudad: Manuela Saez 400. February 1987. M. N. de Richard. Fundación Miguel Lillo (FML 0816); MENDOZA: Dorrego-Guaymallén: Pedro Vargas 847. December 1986. J. P. Richard. Museo Zoologico, Universita di Torino (MZUT R3308). Verified by J. M. Cei (MZUT) and R. F. Laurent (FML). First province records. Extends range 440 km SW Córdoba (Williams and Ghilini 1979. Neotropica 25(74):155-160). The species is locally known as "gepeto." Its distribution is important because in the observed population the association of *H. borellii* with *Triatoma infestans* (Hemiptera: Reduviidae; a Chagas-Mazza disease vector, commonly known as "vinchuca") was evident, a fact already described by Williams and Ghilini (1979 op. cit.) for *Homonota* populations in non-urban areas in Córdoba province. According to that paper, the nymphs of "vinchucas" seem to be an important item in the gecko's diet, and further studies about this lizard's role in the biological control of those bugs are needed.

We wish to thank Mrs. Marta Richard and J. P. Richard for material cited, and Dr. Raymond Laurent and Dr. J. M. Cei for offering valuable suggestions during preparation of this manuscript.

NEW REPTILE RECORDS FOR PAKISTAN

A recent review of the material housed in the herpetological collections of the Zoological Survey of Pakistan has disclosed the presence of two reptile species previously unknown or poorly represented in collections from that country. The latest faunal reviews are by Minton (1969. A contribution to the herpetology of West Pakistan. Bull. Amer. Mus. Nat. Hist. 134:27-184) and Mertens 1969. Die amphibien Und reptilien West-Pakistans. Stuttgarter Beitr. z. Nat. 197:1-96), in which neither species is listed.

SAURIA

AGAMA MINOR (Short-tailed Agama). PAKISTAN: SIND PROVINCE: Thatta District, 20 km N Jungshahi, at Karo Uro. 6 August 1982. Verified by W. Auffenberg. Zoological Survey of Pakistan Collection, Karachi (ZSP 1052). A single adult male (SVL 85, tail 92 mm) of this apparently rare lizard in Pakistan was taken, and is the first definite record with precise locality data known for the country. This species has previously been reported from several scattered localities in northern India (in the states of Maharushtra, Uttar Pradesh, and Gujarat). The only record presumably from Pakistan is without definite locality and simply listed as "Sind" (Smith, M.A. 1935. Fauna of British India. Reptilia and Amphibia, Vol. 2, Sauria. Taylor and Brancis: London). However, within this area Smith lists "Cutch" and "Kathiawar," both of which are clearly in what is now extreme western India near the Pakistan border. Therefore the presence of this species in Pakistan as now conceived is of some importance.

SERPENTES

HYDROPHIS ORNATUS ORNATUS (Cochin Banded Sea Snake). PAKISTAN: SIND PROVINCE: 10 km SW Karachi, in the stunted mangrove forest inland of the barrier beach known as Sand-spit. 9 September 1983. Verified by W. Auffenberg. (ZSP 1923). This species was for many years thought to be restricted to the west coast of India. Mertens (1969, op. cit.) described a single juvenile from Astola Island, near Pasni, Mekkran Coast, Baluchistan, Pakistan. Our specimen is from an area 350 km east of this island and links the Persian Gulf populations (previously thought to be disjunct) with those of western India. It is an adult female with SVL 1635, tail 189 mm.

Submitted by **ZAHIDA PERVEEN,** Zoological Survey of Pakistan, Block 61, PAKISTAN, **FEHMIDA IFFAT,** Secretariate, Shahran-i-Iraq, Karachi 1, PAKISTAN, and **WALTER AUFFENBERG,** Florida State Museum, University of Florida, Gainesville, FL 32611, USA ●

NEW COUNTY RECORDS FOR AMPHIBIANS AND REPTILES OF NORTH CENTRAL TEXAS

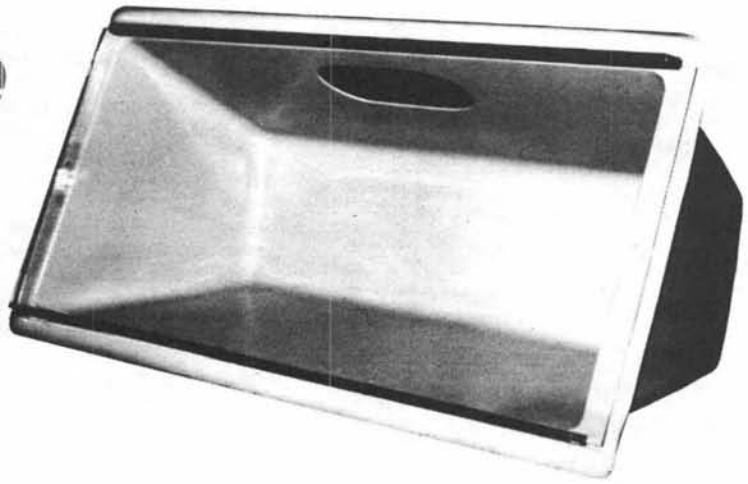
Dixon (1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.) provided a revision of Raun and Gehlbach's (1972. Amphibians and Reptiles in Texas: taxonomic synopsis, bibliography, and county distributional maps. Bull. Dallas Mus. Nat. Hist. 2:1-61) treatise on the herpetofauna of Texas. This extensive and much-needed updating greatly enhances our current knowledge of the distributional patterns of much of the state's 204 species of amphibians and reptiles. Yet, many distributional gaps remain for some well known taxa. Herein I report exclusively new county records (Dixon op. cit.) for seven species of amphibians and reptiles from three counties of north central Texas. Voucher specimens have been deposited in the Arkansas State University Museum of Zoology (ASUMZ). All specimens were collected by the author and identifications were verified by S.E. Trauth.

CAUDATA

AMBYSTOMA TEXANUM (Smallmouth Salamander). Somervell Co: 11.3 km NE Glen Rose, off County Rd 406. 21 March 1987. (ASUMZ 6893-6899). 12.5 km NE Glen Rose, off County Rd 407. 1 May 1987. (ASUMZ 8597). Partly fills hiatus in a four-county area of north central Texas.

ANURA

PSEUDACRIS CLARKII (Spotted Chorus Frog). Hood Co: 19.3 km SE Granbury, off FM 2174 at Russell Ranch. 10 April 1987. (ASUMZ 7069-7072). 18.5 km SE Granbury, off FM 2174 at Hinton-Parker Ranch. 8 May 1987. (ASUMZ 8578). Fills gap between Erath and Johnson counties (Carl 1980. Herp. Rev. 11:116-117).



RANA CATESBEIANA (Bullfrog). Johnson Co: 14.5 km SSW Cleburne on US 67. 17 May 1987. (ASUMZ 8078). 1.6 km SSW Cleburne on US 67 at Lake Pat Cleburne-Nolan River. 13 June 1987. (ASUMZ 8476). Fills hiatus between Ellis, Hood and Somervell counties.

TESTUDINES

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). Johnson Co: 17.5 km SW Cleburne, off US 67 on County Rd 1120 at Georges Creek Ranch. 2 October 1987. (ASUMZ 9103). Partly fills hiatus between Ellis, Parker and Tarrant counties.

KINOSTERNON FLAVESCENS FLAVESCENS (Yellow Mud Turtle). Somervell Co: 2.9 km E Nemo on County Rd 406, near Buck Creek. 16 May 1987. (ASUMZ 8079-8080). 11.3 km NNE Glen Rose on FM 2174, vic. Georges Creek. 17 May 1987. (ASUMZ 8081).

Reptile Cages

FOR THE AMATEUR
OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door is inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $33.95
24" Wide, 12-1/4" High, 12-1/2" Deep
250 sq. in. Floor Area, Single Vent

36" Reptile Cage $58.95
36" Wide, 18" High, 19" Deep
580 sq. in. Floor Area, Double Vent

Prices include freight charges and are shipped via UPS. Institutions, zoos and dealers are invited to write on letterhead for quantity prices.

BOOK REVIEWS

Guía de Campo de los Anfibios y Reptiles de la Peninsula Ibérica, Islas Baleares y Canarias, by Alfredo Salvador (Apartado 1.062, 24.080 León, Spain). 1985. Published by the author. $20 (postage included).

I learned to read from Schmidt and Davis' 1941 *Field Book of Snakes* a few years after it appeared and have since considered field guides an important genre. As a teenager in Spain a decade later, I found that there were no comparable guides and that I had to resort to experts—especially Doris Cochran and her Madrid counterpart Ernesto Cusi—and the technical literature to identify species. Spain got its first usable herpetofauna guide in 1974, and now the same author has written one of the finest guides I have seen. There are 128 good half-page color photographs, including at least one of each species (77 plus 6 marine turtles). The text is profusely illustrated with excellent line drawings and halftones which include the larvae of all 8 salamanders and 15 frogs, and virtually every character state used in the keys. Species receive about one page of text each; treatment of autecology and reproduction is thorough. The bibliography includes approximately 1200 citations (but not Boulenger's 1920-21 *Monograph of the Lacertidae* or Mertens and Wermuth's 1960 *Die Amphibien und Reptilien Europas),* which are well cross-referenced to the species discussions. There are 78 clear distribution maps which show known localities, rather than inferred ranges.

Alfredo Salvador told me that he was disappointed in the way his 1974 guide came out and that he was publishing this one himself to retain editorial control. If he had used a commercial publisher, the 40 page bibliography would have been cut drastically, there would have been many fewer color photographs, and the species discussions would probably have been shortened. The text would have benefitted from careful editing, which few commercial publishers provide. I was irritated by interchangeable use of scientific and capitalized common names. Scientific names were usually italicized, but there are several lapses, as on page 9. Cross-referencing is quite good, except that plate and map numbers are not given in the text, and drawings are not referenced at all, not even in the index. Variation, always a difficult area in popular writing, was not dealt with consistently or effectively; two subspecies of *Gallotia simonyi,* from the Canary Islands, are treated separately, while the more diverse populations of the Balearic *Podarcis lilfordi* and *P. pityusensis* are given capsule descriptions (not because names are lacking). There is a brief statement on variation under each species, but there is no general discussion of population biology. Other topics usually discussed in field guides are here given short shrift (e.g. conservation) or are absent (preservation, snakebite, husbandry). Salvador has achieved the central objectives of a field guide admirably and was not distracted by secondary objectives; the result is very usable, albeit terse. His earlier guide was undoubtedly a factor in the recent renaissance of Spanish herpetology, and this new book will nurture greater interest and facilitate research. Herpetologists elsewhere will find this a useful reference to a diverse and interesting fauna and an entrée to the rapidly growing literature in Spanish and Catalan.

WILLIAM P. MacLEAN
College of the Virgin Islands
St Thomas, U.S.V.I. 00802 ●

A Naturalist in the Environmental Crisis, by Philip W. Smith. 1986. Carlton Press, Inc., New York. 1-131 pp., 16 figures, hardbound. $9.75.

The first seven chapters (74 pages) of this slim volume will be enjoyed by all herpetologists, especially those of us who were fortunate enough to spend our adolescence in the midwest, collecting and observing all the flora and fauna but with a special fondness for herps. Even those who did not have the benefit of coming of age in the prairie peninsula, however, should readily identify with Smith's conclusion as a youth that the books by Raymond Ditmars "were the most interesting. . .ever written" (p. 31). Still, I cannot help but believe that early portions of the text will have more meaning to the native naturalists of the region than to others. For example, in Chapter One Smith has us imagine southern Illinois in the 1920s, when "farms were interspersed among tracts of so-called second-growth forests, locally known as 'woods'. . ." When I read this, I can still recall my mother asking, "Have you been out in the woods again?" with the unsaid concern being, "Oh Lord, what has he brought home this time!"

P.W. Smith, of course, is one of the leading figures in the study of cold-blooded vertebrates in the north-central states. His books, *The Amphibians and Reptiles of Illinois* (1961) and the *Fishes of Illinois* (1979) are model faunistic studies for a state.

Chapters Six and Seven are largely concerned with the period when work on the amphibian and reptile report was in progress.

Herpetologists with a weakness toward any aspect of ichthyology will enjoy Chapters Nine and Ten, the only ones specifically dealing with the Illinois fish report. Anyone with much experience in systematic ichthyology can identify with Smith's reflection that the "sorting was as enjoyable as the collecting, and I wondered why I had resisted the fish survey initially" (p. 104).

Chapter Eight, which mostly concerns collecting in the southwestern United States and Mexico, and Chapter Eleven, in which Smith relates some of his experiences with mammals in this country and abroad, are of general interest to any biologist who has been in those areas or ever hopes to be. What comes through especially in these chapters is the fact that P.W. Smith and his wife Dorothy are students of natural history in the broadest sense.

The final Chapter Twelve is called the "Epilogue," and in these few pages (pp. 117-122) Smith justifies what at first seems a rather curious title for the book. Curious, because, as Smith himself points out, through the late 1950s "the terms 'environmentalist' and 'environmental crisis' were not even in the dictionary" (p. 74). Thus, a good portion of the book consists of episodes that took place during a time when the damage being done to our biota was, if not recognized, at least not widely acknowledged. Smith relates tale after tale of collecting trips in the '40s and '50s where large numbers of animals were collected and sacrificed for museum specimens. He points out that many biologists of the period faced a conflict. "They were reluctant to take more than one or two specimens from a population, but the thinking of the time. . . was that long series (big samples) should be secured" (p. 74). Finally, after completing the fish survey in the 1960s, Smith states, "I had no inclination to convert more live animals into museum specimens" (p. 107).

In the years after World War II, "natural habitats and wildlife were declining, but the trend was so gradual as to be almost imperceptible" (p. 100) and many species even seemed to be increasing in numbers. To a naturalist who had observed changes in extent of habitats over time, however, apparent increase in numbers of a species could often be related to the fact that "wildlife was being concentrated into small areas as the habitats were being fragmented" (p. 74). For this reason, a biologist preparing a faunal survey during the decade or so following World War II probably had "many advantages over those done earlier or later" (p. 74). Earlier, collecting "efforts were rather unproductive and frustrating because there were so many areas of suitable habitat to be sampled and so many hiding places for animals in the undisturbed habitats" (p. 117). The reasons why future surveys may be less productive than those of the postwar era are associated by Smith with continued habitat destruction (pp. 120-121).

Smith, of course, is not the first one to espouse these beliefs. His greatest service in writing this book, and the reason for the title, I

believe, is to show how one naturalist, who grew up in an area which at the time appeared "little exploited" (p. 11) came to the slow but sure realization that he was a witness to and an active participant in the passage of the golden era of natural history studies. Can we not imagine in our nightmares that the role of the biologists who will revise the state faunal reports fifty years hence simply will be to document the continued extinction of the wildlife, using surveys such as Smith's for their baseline data? Smith, reflecting on the relative increase over the years in the numbers of a few ecologically tolerant and aggressive species of fish, could foresee a time "that when most other wildlife was gone from the earth there would still be people and a few species of fishes" (p. 95).

I found a number of typographical errors in this short book: "particualrly" on p. 40, "Horsehose" (= Horseshoe) on p. 67, 'cuntry" on p. 70, "visitd" on p. 113, and "accuratley" on p. 120. Other curiosities include the fact that Smith's birth year (1921 according to the cover of *Fishes*. . .) is never stated, although the birth of his sister in 1933 is mentioned in the only sentence that reference to her is made in the book (p. 22). On p. 23, Smith writes about the period in the Depression when his "mother was a widow again" which surprised me because the fact that his mother had been widowed previously had not been mentioned.

These minor criticisms do not detract from this book of personal reminiscences by a noted biologist on a productive career that spanned an important era of the ongoing "environmental crisis." All students of natural history and conservation could benefit from reading this book, and, of course, herpetologists and ichthyologists everywhere should obtain a copy.

Handbuch der Reptilien und Amphibien Europas (in German). Wolfgang Böhme, Editor, 3 vols. Band 1 - Echsen, 1981, 520 pp, 91 figs. Band 2/I - Echsen II (Lacerta), 1984, 416 pp, 47 figs. Band 2/11 (Podarcis), 1986, 434 pp, 64 figs. Price DM 216 for each volume. Available from AULA-Verlag GmbH, Postfach 1366, D-6200 Wiesbaden, Federal Republic of Germany.

The Handbuch der Reptilien und Amphibien Europas is an undertaking of major proportions. The purpose of these volumes is to present detailed accounts of all of the species of amphibians and reptiles known to occur in Europe. The first three volumes deal with lizards; four volumes in preparation will concern the snakes, turtles, salamanders, and anurans, respectively.

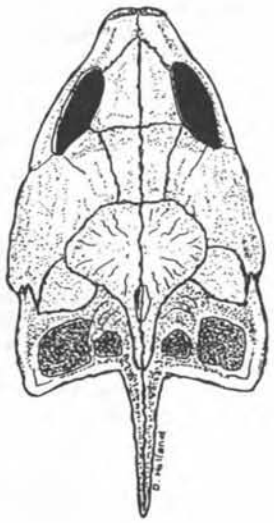
These volumes are sturdily bound in buckram; the single column format of clear type is on good white paper trimmed to 15 X 23 cm. The black and white illustrations generally are excellent. Each species account is authored individually; 27 authors contributed the 68 species accounts of lizards. The editor, Wolfgang Böhme, is responsible not only for the high quality and conformity of the accounts but also for the introductory material in Band 1 and keys to the families and genera.

Band 1 contains accounts of five genera and seven species of Gekkonidae, two genera and six species of Agamidae, one genus and one species of Chameleonidae, two genera and two species of Anguidae, four genera and six species of Scincidae, and five genera and ten species of Lacertidae. Some readers will disagree with the inclusion of the Amphisbaenidae (one genus and one species) in the lizards. Band 2/I is devoted to the 18 species of *Lacerta*, and Band 2/II includes the 17 species of *Podarcis*.

The accounts vary from 7 to 54 pages in length. Each contains a detailed diagnosis, a lengthy description (including osteology and karyology in some accounts), geographic distribution, ecology, life history, food, population dynamics, behavior, synonyms, and where appropriate a section on geographic variation. Each account stands alone as an independent review with its own literature cited. Each account contains a detailed spot map indicating the distribution of the species. Some accounts contain drawings of scutellation, skulls, and appropriate graphs. Subspecies are treated simply as a list of subspecific names and geographic distribution of each.

Variation in the thoroughness of the accounts depends mostly on the availability of information. The accounts of well-known and wide-ranging species (e.g., *Lacerta viridis* and *Podarcis muralis*) are lengthy and contain a great deal of information on various aspects of the biology of the species, whereas accounts of other species of limited distribution and not so well known (e.g., *Alsophylax pipiens* and *Cyrtodactylus caspius*) are much shorter. In general, the accounts are of high quality and good organization. Comparable information can be located readily in each account.

North American herpetologists immediately will compare the Handbuch with the accounts that have been published in the "Catalogue of American Amphibians and Reptiles." Whereas the accounts in the American catalogue provide an introduction to the literature on each species, the accounts in the European Handbuch provide a detailed review of each species. Thus, the latter is much more extensive than the American catalogue.



The usefulness of the Handbuch would have been enhanced with the addition of two things: (1) good photographs of living animals and (2) detailed synonymies including type localities and location of type specimens. Granted, good photos of most species are available in any one of several popular books on the European herpetofauna, but a detailed treatise on the lizard fauna should contain adequate photographs. The Handbuch is an obvious place for a worker to seek information on synonymies and type specimens. These data are available for some species in certain checklists, whereas such data on other species are not readily found in the literature. Furthermore, in those accounts dealing with species displaying notable geographic and/or ontogenetic differences in color pattern, it would be helpful to have these illustrated.

The authors, editor, and publisher are to be congratulated on the production of three excellent volumes on European lizards. These books are indispensible for anyone with an interest in European lizards; they are essential for the museum systematist and extremely useful to persons using any of the species in experimental work or maintaining these animals in captivity. I look forward to the publication of the remaining volumes in the series.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1988

Student member	$20.00*	Sustaining member	$50.00*
Regular member	$27.00*	Contributing member	$75.00*
Institutional	$50.00*		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

SSAR BUSINESS

PROPOSAL TO INCLUDE THE RED-EARED TURTLE (*Trachemys scripta elegans*) IN APPENDIX II OF CITES

The Conservation Committee of SSAR supported listing *T. s. elegans* in Appendix II of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES). This action was taken on 30 January 1987 in a letter to Dr. Charles W. Dane of the Office of the Scientific Authority of the U.S. Fish and Wildlife Service. I wish to correct a statement in *Herpetological Review* (18(4):62) saying (in a summary of the 30th Annual Meeting of SSAR/HL in Veracruz, Mexico) that the Conservation Committee had not supported this listing.

The proposal to list *T. s. elegans* was spearheaded by the International Wildlife Coalition (1807 H Street N.W., Washington, D.C. 20006) with abundant support by numerous individuals and organizations (including SSAR) in the herpetological community. Supporters cited concern about declining populations of the red-eared turtle and the practice by turtle farms of replacing breeding stock from wild populations to supply several million individuals per year of these turtles in international trade.

Despite much more support for the proposal than against it, the U.S. Scientific Authority decided not to propose the red-eared turtle for inclusion in CITES Appendix II at the 1987 Meeting of the Parties. The proposal, however, will be updated and submitted again prior to the 1989 CITES meeting. Herpetologists desiring a full statement documenting the proposal and who have a concern for this issue should contact the International Wildlife Coalition (address above) for more information.

WILLIAM S. BROWN
Past Chairman, Conservation Committee ●

MAC-WISE? SSAR NEEDS *YOU*!!

As *Herp. Review* moves into the era of desktop publishing, the editorial staff is seeking a computer-wise volunteer to assist with the formatting of each quarterly issue. The volunteer (henceforth known as a Managing Editor) must be familiar with the MacIntosh computer and have access to a MacPlus with either MacWrite or Microsoft Word 3.01. Access to a good quality laser printer would be useful, but not necessary. The volunteer would not be doing the initial inputting—only the final formatting from a disc delivered by mail. Support will be available from SSAR members familiar with these systems.

Interested? Please contact the editor by mail or telephone (216-368-3558). ●

ERRATUM

In the Annual Meeting report which appeared on p. 62 of the December 1987 issue of *Herp. Review*, incorrect/incomplete addresses were printed for the recipients of the 1987 Kennedy Award. Marc P. Hayes (correct address: Department of Biology, University of Miami, Coral Gables, Florida) and Mark R. Jennings (correct address: The University of Arizona, Tucson. Current address: U.S. Fish and Wildlife Service, Los Banos, California) co-authored the winning paper "Decline of ranid frog species in Western North America: Are bullfrogs (*Rana catesbeiana*) responsible?" which appeared in the December 1986 issue of *Journal of Herpetology*. The editor regrets the error. ●

NEWSNOTES

JAMES C. LIST HERPETOLOGICAL COLLECTION

The Museum of Natural History at The University of Kansas, Lawrence, has acquired the herpetological collection of Dr. James C. List, Ball State University, Muncie, Indiana. This collection of 2,500 specimens of amphibians and reptiles is the result of decades of field work by Dr. List and his colleagues and students, and is considered the finest collection of its kind for the Jackson Purchase region of southwestern Kentucky and adjacent states. With the acquisition of this collection, plus private collections donated earlier to KU by Joseph T. Collins, Corson J. Hirschfeld and others, the Museum now houses substantial holdings of Kentucky amphibians and reptiles.

As soon as the specimens in the List collection are sorted and catalogued, they will be available for loan. ●

MEETINGS

ASZ MEETING

The 1988 Annual Meeting of the American Society of Zoologists with the American Microscopical Society, Animal Behavior Society, The Crustacean Society, International Association of Astacology, Society of Systematic Zoology, and the Western Society of Naturalists will be held at the Hilton Hotel and Towers in San Francisco, California, during the traditional post-Christmas period, 27-30 December 1988.

The Call for Contributed Papers has been issued by ASZ, and an *August 8* deadline for receipt of abstracts of papers (oral or poster presentations) has been set.

Symposia presently scheduled which may be of interest to herpetologists include: (1) Recent Developments in the Study of Animal Migration, (2) Parasites and Sexual Selection, (3) Evolving Concepts of Chemical Mediation: A Symposium in Honor of Howard A. Bern, (4) Concepts of Efficiency in Biological Systems, (5) Concepts of Adaptation in Aquatic Animals: Deviations from the Terrestrial Paradigm, (6) Cellular and Molecular Biology of Pattern Formation, (7) History of Regeneration Research, (8) Science As A Way of Knowing—Cell and Molecular Biology, (9) Workshop on Science Comes to California, and (10) Workshop on Research-Education at Small Colleges and Universities: Quality Science on a Frayed Shoestring.

Meeting plans include several socials, special programs, commercial exhibits and a Job Placement Service. Hotel rates are $66 for single, double, triple or quad rooms at the Hilton Hotel and Towers. Housing and Registration deadlines are 20 November. Forms will be available mid-September.

This meeting is hosted by the California Academy of Sciences, with Daphne G. Fautin and Ralph I. Smith co-chairing the Local Arrangements Committee. For more information contact: Mary Adams-Wiley, Executive Officer, American Society of Zoologists, 104 Sirius Circle, Thousand Oaks, California 91360, USA. (805) 492-3585. ●

FEATURES

MORTALITY IN *Ambystoma maculatum* LARVAE DUE TO *Tetrahymena* INFECTION

During the spring of 1984, *Ambystoma maculatum* (spotted salamander) eggs were collected from three ponds in Marquette County, Michigan, for studies on the effects of acid precipitation on larval development (Ling, VanAmberg, and Werner 1986). Within 1-3 days after hatching, swelling of the epidermis was observed on the head and/or chest region of larvae from two of the ponds (Fig. 1). Viewed at 10X, ciliates were seen to completely fill the swollen area under the epidermis. The ciliate (Fig. 1, insert), averaging 47 x 27 μ (N=22), was tentatively identified as *Tetrahymena pyriformis* (Corliss, 1973), based on body size and lack of caudal cilium. A positive species identification requires selective histological staining and/or biochemical tests, and was not done.

One hundred and twenty larvae were hatched from pond 1, of which 31 infected larvae died within 7 days. At pond 2, 10 of 64 larvae had *Tetrahymena* present under the epidermis; all 10 larvae died within three days. No evidence of *Tetrahymena* parasitism was observed in larvae hatching from pond 3. Examination of freshwater from ponds 1, 2 and 3 revealed a similar shaped free-living *Tetrahymena* in ponds 1 and 2, but not pond 3.

In all cases where *Tetrahymena* parasitism was observed, larvae usually died within 24 hours. Swelling of the epidermis spread down the dorsal region of the larvae in the late stages of infection, causing larvae to coil ventrally. Histological examination of preserved *A. maculatum* larvae revealed concentrations of *Tetrahymena* in nervous tissue. No *Tetrahymena* were observed in histological sections of larvae that were not infected at the time of hatching.

Shumway (1940) reported *Glaucoma* sp. in the central nervous system of *A. texanum* in the laboratory. Corliss (1960), however, suggested that the *Glaucoma* sp. Shumway reported was either *T. corlissi* or *T. pyriformis*. Speidel (1953) reported a *Balantidium* sp., later identified as *T. corlissi* (Thompson and Speidel 1955; Thompson 1955) infecting bruised or wounded embryonic and larval stages of the amphibians *Bufo, Rana,* and *Hyla*. The same species was reported from the larvae of *Pseudotriton* (Thompson 1955) and *Pseudacris* (Speidel 1958).

T. pyriformis has been found in egg masses and developing embryos of *A. maculatum,* but its effect is unknown (Corliss 1954). Assuming this parasite is *T. pyriformis,* this is the first reported instance of mortality to *Ambystoma maculatum* larvae, apparently due to effects on the central nervous system.

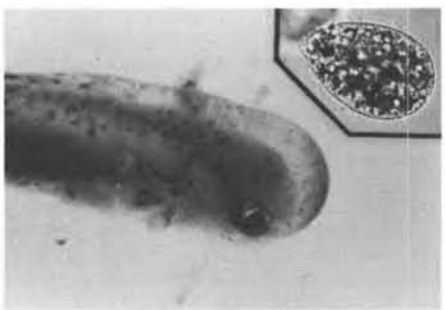

Figure 1. *Ambystoma maculatum* larva showing epidermal swelling surrounding the head and gill region. The swollen area was filled with the ciliate (insert) tentatively identified as *Tetrahymena pyriformis.*

RECORD LENGTHS FOR SOME AMPHIBIANS AND REPTILES FROM THE WESTERN UNITED STATES

The following list provides unrecorded length records noted in the field, at the Museum of Vertebrate Zoology (MVZ), and at San Jose State University (SJSU). An asterisk denotes uncollected specimens, representing protected species, or those found in a protected area.

AMBYSTOMA GRACILE GRACILE (Brown saamander). SJSU A2458, no collection data. Sexually mature, neotenic male, 132 mm SVL, 256 mm TTL. Exceeds record of 21.9 cm (Behler and King 1979:290).

BATRACHOSEPS PACIFICUS SSP*. (Gabilan slender salamander). Measured 2 Feb 1986 by J. Boundy and A.W. Ford, at the East entrance to Pinnacles Nat. Mon., San Benito Co., CA. SJSU photo 1. Sex unknown, 59 mm SVL, 157 mm TTL. Exceeds record of 14 cm (Behler and King 1979:307).

*BATRACHOSEPS SIMATUS** (Kern Canyon slender salamander). Measured 22 March 1987 by J. Boundy and A.W. Ford, at Stork Cr., Kern River Can., Kern Co., CA. SJSU photo 8. Sex unknown, 54 mm SVL, 130 mm TTL. Exceeds record of 12.5 cm (Behler and King 1979:309).

*BATRACHOSEPS STEBBINSI** (Tehachepi slender salamander). Measured 2 March 1986 by J. Boundy and A.W. Ford, at Caliente Cr., 4.8 km W of Loraine, Kern Co., CA. SJSU photo 2. Female, 60 mm SVL, 127 mm TTL. Exceeds record of 12.2 cm (Behler and King 1979:310).

*ENSATINA ESCHSCHOLTZII KLAUBERI** (Large-blotched ensatina). Measured 30 March 1985 by J. Boundy and A.W. Ford, at Cuyamaca Rancho, San Diego Co., CA. SJSU photo 3. Male, 152 mm TTL. Exceeds record of 150 mm (Bishop 1943:295).

*ENSATINA ESCHSCHOLTZII XANTHOPTICA** (Yellow-eyed ensatina). Measured 27 March 1979 by J. Boundy and W.P. Hutchins, at Sunol Regional Park, Alameda Co., CA. SJSU photos 4 and 5. Male, 75 mm SVL, 159 mm TTL. Female, 83 mm SVL, 154 mm TTL. Both exceed record of 137 mm (Cochran and Goin 1970:40).

BUFO BOREAS HALOPHILUS (California toad). SJSU A1579, Fallen Oak Dr., San Jose, Santa Clara Co., CA. Collected 14 May 1985 by D.L. Martin. Female, 124 mm SVL. Exceeds record of 122 mm (Karlstrom 1962:68).

BUFO RETIFORMIS (Sonoran green toad). SJSU A1312, 86.4 km (by road) E of Why, Pima Co., AZ. Collected 28 July 1981 by T.G. Balgooyen and J. Boundy. Female, 60 mm SVL. Exceeds record of 5.7 cm (Behler and King 1979:396).

PHRYNOSOMA CORONATUM FRONTALE (California horned lizard). SJSU R1192, 1.6 km W of Fat City, near the mouth of Clear Cr., San Benito Co., CA. Collected 25 May 1979 by J. Boundy and W.P.Hutchins. Female, 115 mm SVL, 152 mm TTL. Exceeds record of 89 mm SVL (Smith 1946:297).

PHRYNOSOMA MCCALLI (Flat-tailed horned lizard). SJSU R178, Baja California Norte, MEX. Collected 1957 by R. Hassur. Female, 87 mm SVL, 143 mm TTL. Exceeds record of 81 mm SVL (Smith 1946:308).

SAUROMALUS OBESUS OBESUS (Western chuckwalla). SJSU R215, Randsburg City Dump, near Last Chance Can., Kern Co., CA. Collected 12 April 1960 by E. Harrington.

Male, 222 mm SVL, 457 mm TTL. Exceeds record of 220 mm SVL (Berry 1974:31).

CNEMIDOPHORUS TIGRIS TIGRIS (Great Basin whiptail). SJSU R3060, 11.5 km N of Kelso, San Bernardino Co., CA. Collected 24 May 1986 by J. Boundy and A.W. Ford. Male, 104 mm SVL, 387 mm TTL. Exceeds record of 95 mm SVL (Smith 1946:421).

CNEMIDOPHORUS TIGRIS MUNDUS (California whiptail). SJSU R449, Pinnacles Nat. Mon., San Benito Co., CA. Collected 23 April 1951 by A. Browne. Male, 107 mm SVL, 372 mm TTL. Exceeds record of 105 mm SVL (Smith 1946:427).

ELGARIA COERULEA COERULEA (San Francisco alligator lizard). SJSU R483, Big Basin, Santa Cruz Co., CA. Collected Summer 1939 by R. Pisano. Female, 119 mm SVL. Exceeds record of 108 mm (Fitch 1938:414).

ELGARIA MULTICARINATA MULTICARINATA (California alligator lizard). SJSU R3822, no collection data. Male, 153 mm SVL. Exceeds record of 144 mm (Fitch 1935:21).

*LEPTOTYPHLOPS HUMILIS SEGREGUS** (Trans Pecos blind snake). Measured 3 June 1981 by J. Boundy and W.F. Meyers, at 36.8 km N of Panther Junction, Big Bend Nat. Park, Brewster Co., TX. SJSU photo 6. Female, 333 mm TTL. Exceeds record of 330 mm (Tennant 1984:71).

CHILOMENISCUS CINCTUS (Banded sand snake). SJSU R2116, 184 road km W of Santa Rosalia, Baja California Norte, MEX. Collected 2 May 1985. Male, 229 mm SVL, 261 mm TTL. Exceeds record of 25.4 cm (Behler and King 1979:593).

DIADOPHIS PUNCTATUS AMABILIS (Pacific ringneck snake). SJSU R3042, Skyline summit, 1.6 km NW of Saratoga Gap, Santa Cruz Co., CA. Collected 15 May 1986 by A. Wolf. Female, 449 mm SVL, 532 mm TTL. Exceeds record of 20 inches (Wright and Wright 1957:163).

DIADOPHIS PUNCTATUS REGALIS (Regal ringneck snake). Preserved specimen in the collection of Harry W. Greene, MVZ, obtained by W.F. Meyers on Fort Huachuca, Cochise Co., AZ. Sex unknown, 857 mm TTL. Exceeds record of 76.2 cm (Behler and King 1979:600).

*GYALOPION CANUM** (Chihuahuan hooknosed snake). Measured 1 June 1981 at 1.6 km N of Persimmon Gap, Big Bend Nat. Park, Brewster Co., TX, by J. Boundy and W.F. Meyers. SJSU photo 7. Female, 384 mm TTL. Exceeds record of 36.2 cm (Behler and King 1979:612).

HYPSIGLENA TORQUATA CHLOROPHAEA (Sonoran night snake). SJSU R1216, 4.8 km W of Ortiz, Sonora, MEX. Collected 12 Aug. 1976 by J. Moore. Female, 507 mm SVL, 598 mm TTL. Exceeds Record of 20 inches (Wright and Wright 1957:324).

HYPSIGLENA TORQUATA KLAUBERI (San Diego night snake). SJSU R1404, hwy 79, at the head of Cuyamaca Lk., San Diego Co., CA. Collected 3 Sept. 1983 by J. Boundy and W.P. Hutchins. Female, 368 mm SVL, 433 mm TTL. Exceeds record of 16 inches (Wright and Wright 1957:320).

HYPSIGLENA TORQUATA NUCHALATA (California night snake). MVZ 179786, Corral Hollow, 7.4 km W of the county line, Alameda Co., CA. Collected 24 May 1982. Female, 365 mm SVL, 420 mm TTL. Exceeds record of 14 inches (Wright and Wright 1957:322).

LAMPROPELTIS PYROMELANA PYROMELANA (Arizona mountain kingsnake). SJSU R640, Mt. Lemon Rd., 7.5 km N of Tanque Verde Rd., Pima Co., AZ. Collected 17 Aug. 1977 by T. Rado. Male, 907 mm SVL, 1088 mm TTL. Exceeds record of 104.1 cm (Behler and King 1979:621).

MASTICOPHIS TAENIATUS TAENIATUS (Desert striped whipsnake). SJSU R665, Siskiyou Co., CA. Collected Fall 1955 by P. Gordon. Male, 1150 mm SVL, 1652 mm TTL. Exceeds record of 61 inches (Wright and Wright 1957:453).

PITUOPHIS MELANOLEUCUS CATENIFER (Pacific gopher snake). SJSU R1438, hwy 152 at the NW end of San Luis Res., Merced Co., CA. Collected 29 May 1976 by J. Boundy. Female, 1661 mm SVL, 1905 mm TTL. Exceeds record of 1854 mm (Klauber 1947:16).

TANTILLA NIGRICEPS (Plains black-headed snake). SJSU R2193, 6.4 km S of Apache, Cochise Co., CA. Collected 17 Aug. 1985 by W.P. Hutchins and W.F. Meyers. Male, 320 mm SVL, 384 mm TTL. Exceeds record of 37.5 cm (Behler and King 1979:658).

CROTALUS CERASTES CERASTES (Mojave Desert sidewinder). SJSU R3216, 4.8 km S of Kelso, San Bernardino Co., CA. Collected 24 May 1986 by A.W. Ford. Female, 597 mm SVL, 637 mm TTL. Exceeds record of 587 mm (Klauber 1972:175).

BREEDING ACTIVITIES OF THE HELLBENDER IN MISSOURI

The last description of hellbender (*Cryptobranchus alleganiensis alleganiensis*) breeding activities based on extensive sampling during the breeding season was by Smith (1907, 1912a). This study involves making such observations for the entire length of the breeding period concurrently with a study of movement and dispersal. Except in the Spring River, Arkansas (unpublished data), hellbenders breed from late summer to early fall, mostly September, throughout their range (cf. Nickerson and Mays 1973). Males can be distinguished by enlarged cloacal glands during that time (Reese 1904). Fertilization is external (Smith 1907).

From 4 September to 7 November 1985, 21 surveys were made in a 100 m section of the Niangua River, Laclede County, Missouri. Hellbenders were caught by hand during daylight by overturning rocks, reaching into crevices, and occasionally breaking bedrock with a crowbar. An attempt was made to reposition rocks. An average ($\pm$ SE) of 9.7 $\pm$ 1.1 males and 16.2 $\pm$ 0.9 females was captured per survey. Newly captured individuals were marked by heat-branding before being released. No juveniles were captured.

On 11 September, a male and female were observed under the same rock for the first time during the study. On 13 September, two males were observed expelling milt upon capture. On 16 September, a clutch of eggs was found in the open near the bank. Neither eggs placed in an aquarium nor those left in the stream from this clutch exhibited any development; the eggs were likely not fertilized. Also, a male and female were found under a single rock, and two females and a male were found in contact with each other in a hole in the bedrock. A rock covered most of the opening of the cavity.

At 1020 h on 18 September, 13 hellbenders were observed nestled together in a narrow strip about 1 m long extending parallel to the stream flow between rocks. A few of these occluded a hole in the bedrock; only their heads were exposed. An egg string trailed from the cavity. Eleven of the 13 were males. Six of them had not previously been captured, so they were placed in a sack for marking. The hole extended farther into the bedrock than I could reach. At 1545 h, after the day's sample had been completed, 8 hellbenders were observed at the same location, including 3 more unmarked individuals. When hellbenders occluding the hole were removed, others took their place, and those gently removed would try to return rather than attempt to escape. Besides these animals, several other hellbenders were caught in the open rather than under shelters. Two hellbenders were observed to inspect holes in a mud-gravel bank, and one was repulsed (snout bitten) by another hellbender occupying a hole. Moreover, while I was branding on the bank, two males at different times walked into the shallows ($<$ 20 cm; I never saw a hellbender there before or after) where the sack containing the unmarked animals was fastened. A female had released some eggs in the nylon mesh sack. Each male appeared to inspect the sack before returning to deeper water. Within the study site, 49 hellbenders were captured that day, 19 more than in any other single day. Fourteen of the 26 new captures were never seen again. This was one of two surveys where males (28) outnumbered females. On the last survey, 11 of 15 were males. Nine of the males plus two females were captured by breaking bedrock on that date.

On 24 and 26 September, an individual was found with a short egg string extending from the cloaca, and a male and female were captured (under the rock covering the hole in the bedrock) where three hellbenders were caught on 16 September. The male had been there on the earlier date but not the female. One of the females of that earlier date was under a rock 24 m downstream on 24 September, sharing the rock with a different male. On 1 October, two hellbenders had egg strings protruding, and a different male and female were found under one rock. This was the last time that more than one hellbender was caught under a single shelter. On 6 October, two females with eggs trailing from their cloacae were observed for the final time.

On 7 October, the snout of a hellbender was observed in the entrance (about 10 cm wide) of a hole in the mud-gravel bank previously mentioned about 15 cm below the surface. The hellbender was not caught, the hole being too extensive, but embryos of two different clutches (based upon stage of development) were found. Developmental stages were approximately 13 and 17 or about 11 and 15 days old (Smith 1912b).

On 2 November, nine hatchlings measuring 25-27 mm total length were removed from this hole. One that was still half within the gelatinous envelope measured 27 mm, thus I inferred that the others were newly hatched. Embryos were also observed on 6 October at the entrance to an extensive cavity under the bedrock and were found with adult males on 15 October and 7 November by breaking bedrock; none represented an entire clutch. Continued flooding after the latter date prevented further sampling.

DISCUSSION

As suggested by Ingersol (1982), the breeding season in the Niangua seemed to extend from the second week of September through the first week of October. Dundee and Dundee (1965), however, found eggs in the Niangua on 3 September 1954, and on 14 November they collected two ripe females. Ingersol (1982) reported that 27.5% of the Niangua females did not spawn and that their ova were atretic. This may explain the collection of ripe females in November.

Smith (1907) reported diurnal congregations of 6-12 hellbenders during the breeding season. Several times he observed them "to pile up in crevices between rocks, two or three lying alongside each other, or two or more trying to force their way into the same crevice." Bishop (1941) stated that these activities were apparently a "kind of nuptial congress" to stimulate mating. He similarly observed a male return to a nest (occupied by three other males) after it was thrown about 6 m upstream. Males are usually found in possession of nests after spawning rather than females (Smith 1912a). The attraction of two males to the capture sack fastened in the shallows in this study suggests that olfactory signals are probably important in these mating activities.

There is only one report in the literature of hellbenders using a cavity in the bank for shelter and spawning (Nickerson and Tohulka 1986), and it was a crevice in bedrock along which there was no noticeable current. In contrast, I found a nest cavity at the base of a 2-m high mud-gravel bank that was slowly being eroded by a moderate current. The defense of a similar cavity as observed on 18 September was not unexpected. Hillis and Bellis (1971) reported that released animals were repulsed when they sought shelter occupied by another hellbender, and both Smith (1907) and Bishop (1941) described the vicious defense of a nest by one male against other hellbenders. Further, fierce defense of shelters has been observed in large river aquaria (Karen McKinnis and Robert Wilkinson, pers. comm.).

Smith (1912a) stated that he found relatively few eggs that were not fertilized. However, besides the Niangua clutch that did not develop, I have found clutches in the Spring River, Arkansas, that also did not seem to be fertile. Unlike the nonfertile clutch, the embryos found under bedrock did not represent an entire complement of about 170-650 eggs (Topping and Ingersol 1981). Whether some had been swept away or were eaten is unknown. Both sexes will consume ova (Smith 1912a).

Bishop (1941) reported that eggs deposited 3-17 September hatched between 7-14 November in northwestern Pennsylvania, and the hatchlings were 27-33 mm long. He also reported that more than one female may lay eggs in the same nest. The hatchlings found in this study are believed to have been no more than 45 days old. Temperature is undoubtedly a major factor in determining the length of the embryonic period and possibly the size at hatching.

HERPETOLOGY IN HUNGARY

Hungary has never been an important center for herpetological research for several reasons. In the entire country there are only 16 species of amphibians and 15 species of reptiles. Our geographical situation and world political position, such as the absence of possessions, contribute to the general lack of professional interest in herpetology. Lajos Mehely (1862-1953) is probably the best known Hungarian herpetologist.

The official center for herpetological research is the Herpetology Department of the Hungarian Natural History Museum of Budapest. Only a few other scientists conduct herpetological research. Working mostly on their own, without benefit of colleagues in their own institutions, their research follows mostly ecological, faunistic, taxonomic and toxicological themes. Unfortunately, herpetology in Hungary has neither a unifying organization nor its own periodical. The more significant papers are scattered primarily in the following periodicals: Allattani Kozlemenyek, Vertebrata Hungarica, Acta Zoologica, and Acta Biologica Szegediensis. Only rarely are Hungarian authors able to publish in foreign herpetological periodicals.

Officially, all herpetofauna in Hungary are under total protection as a means of conservation. Hungary is also a member of the "Washington Convention" since 1985. Several notable herptiles which are found in our country include: *Ablepharus kitaibelii fitzingeri* (Mertens), *Coluber jugularis caspius* (Gmelin), and *Vipera ursinii rakosiensis* (Mehely).

The once rich herpetofauna of Hungary has suffered reductions in population sizes, as is the case in many parts of the world. The primary reason for this is large scale farming and increased use of chemicals. Also, in the early 1960s, animal collecting campaigns accompanied the land-drainage programs in some of the marshy habitats. Today, all habitats which are home to the meadow viper are under strict protection, and some smaller "Sanctuaries" are completely fenced to protect the species. Nevertheless, there is much to be done to promote conservation techniques which will support population growth of this viper.

In 1985 and 1987, Mr. Keith F. Corbett and several other herpetologists visited Hungary on behalf of the Conservation Committee of the Societas Europea Herpetologica. Their purpose was to advise on the means of habitat protection for *V. ursinii rakosiensis*, as well as to help in determining the current population status of this species.

The First Herpetological Congress of Socialist Countries, in 1981, was the most important herpetological event in Hungary in the last decade. It was organized by Mr. Oliver Gy. Dely and was attended by a number of prominent herpetologists, including several from the Western Hemisphere. This meeting was extremely valuable in promoting interchange among scientists from different countries.

In recent years, the keeping of amphibians and reptiles by amateurs has become more widespread than ever before. Individual pet keepers have not been able to successfully form any major herpetological societies. There are about five or six organized amateur groups in the country, but their membership is small and they function only sporadically. The most reliable of these groups is the "Herpetological Studio" in the town of Érd; this group publishes the periodical *Terrarium*.

The total number of amateur and professional herpetologists in Hungary is estimated to be about one hundred individuals, but only a dozen or so can be considered scientists.

A proposal has recently been made to create a herpetological section within the National Environment and Nature Protection Office, in order to help coordinate the herpetological activities occurring within our country. Possible activities of this office include establishing training camps for youths interested in amphibians and reptiles and preventing the destruction of frogs and toads as they cross roads to reach their breeding site.

Very few books in the area of herpetology are published in the Hungarian language. In order to remain current in the field, amateur and professional herpetologists must read literature in English, German, or Russian. Only ten books relating to herpetology were published in Hungarian in the last twenty-two years, and most of these were popular/educational books.

Current trends indicate that there will be increasing numbers of both amateur and professional herpetologists in the near future in our country and we anticipate significant advances in Hungarian herpetology.

ACKNOWLEDGMENTS

I am thankful to T. Fehér, L. Gergelics, P. Keresztesy, M. Marián and Z. Takács for their helpful suggestions, and to Miss Á. Téglasy for correcting the manuscript.

CAPTIVE REPRODUCTION OF THE SAN FRANCISCO GARTER SNAKE *Thamnophis sirtalis tetrataenia*

The San Francisco garter snake *Thamnophis sirtalis tetrataenia* is a peninsular race of the common garter snake endemic to the San Francisco Peninsula and known only from San Mateo County, California (Fox 1951; Barry 1978). It is currently listed as endangered by the U.S. Fish and Wildlife Service, the International Union for Conservation of Nature and Natural Resources (I.U.C.N.), and the California Department of Fish and Game. The status of wild populations has been reported by Bury (1971), Medders (1976), and Barry (1978).

On 7 March 1983, the Dallas Zoo (D.Z.) and the Fort Worth Zoo (F.W.Z.) received a group of confiscated *T. s. tetrataenia*. Captive reproduction for this subspecies has not previously been reported. Data on six captive breedings of *T. s. tetrataenia* are presented here.

MATERIALS AND METHODS

Each zoo received three juvenile snakes and one subadult. The snakes represent two broods from two wild-caught, gravid females originally collected in the Pescadero Creek area of San Mateo Co., California (K. McCloud, pers. comm.). The juveniles were believed to be siblings from one wild-caught, gravid female, and the subadults siblings from another wild-caught, gravid female. Therefore, two different broodlines were available for breeding.

Sexing revealed a ratio of one juvenile male, one subadult male, and two juvenile females (F.W.Z.); and three juvenile males and one subadult female (D.Z.). Fecal examination revealed the presence of a coccidea infestation in all of the snakes, which was treated with daily oral administration (injected into the food items) of sulfamethazine at a dosage of 75 mg/kg body mass for seven days.

Initially caging consisted of plastic shoe boxes (29.5 cm x 15.0 cm x 9.0 cm), 1 gallon glass jars, or five gallon aquaria (36.0 cm x 22.0 cm x 26.0 cm). Paper was used as a substrate and plastic hide boxes, pieces of bark, or plastic leaves provided security. This type of caging was also used for rearing neonates. As the snakes grew, they were moved to larger off-exhibit aquaria; or to sweater boxes. Paper substrate and similar props were again used. The Reptile Department staff of each zoo prepared a public display for this species. Exhibit cages were modular fiberglass tanks with gravel substrate and rocks, weathered pieces of wood, and plastic plants as props. Breeding and parturition occurred in off-exhibit aquaria (36.0 cm x 22.0 cm x 26.0 cm) at F.W.Z. and in the display exhibit (36.5 cm x 74.0 cm x 36.5 cm) at D.Z.

Water was available ad libitum. Caging and water bowls were disinfected when necessary with Roccal-D (Winthrop Laboratories) diluted 1:400 in hot water.

Exhibit cage lighting at D.Z. was provided by two 2-foot 20 W "Cool White" fluorescent bulbs (Sylvania). A 75 W incandescent reflector spotlight (Westinghouse) was used to provide a basking spot for gravid females. Off-exhibit lighting was provided by "Cool White" fluorescent bulbs above the work area with skylights providing additional lighting for all cages. Cage lighting at F.W.Z. was provided mainly through skylights. No direct artificial lighting was provided for off-exhibit snakes except for a 50 W spotlight over the breeding cage. Snakes at both zoos were exposed to the natural photoperiod for the Dallas-Fort Worth area via skylights. Artificial lighting photoperiod was varied through the year to correspond to the local natural photoperiod.

Ambient temperatures varied from 27-30° C (D.Z.) and 21-32° C (F.W.Z.) during the warmer months. Incandescent spotlights over cages housing gravid females produced "hot spots" for basking with maximum temperatures of 32° C. Snakes at both zoos were subjected to three-month cooling periods (December-February) to simulate the natural hibernation cycle prior to breeding. At D.Z. temperatures were lowered 2° C/day until a low of 13° C was attained. Beginning in mid-February, temperatures were raised 2° C/day until 27° C was attained. At F.W.Z., snakes were subjected to greater temperature fluctuations ranging from 13-30° C (mean 20.6° C during the cooling cycle). Daily fluctuations ranged from 2-13° C (mean 7.5° C). Water was constantly available during the cooling cycle; no food was offered to the snakes during this time.

Snakes at F.W.Z. were fed a diet consisting of fish (golden shiners *Notemigonus cyrsoleucas*, goldfish *Carassius auratus*, and guppies *Lebistes reticulatus*), frogs (*Acris crepitans* and *Rana pipiens*) and earthworms (*Lubricus* sp.). Frequency of feeding varied from every other day (young snakes) to 2-3 times a week (adults). Depending upon size, specimens were fed either whole or pieces of food items (offered from forceps).

At D.Z. the diet consisted of fish (goldfish *Carassius auratus*, guppies *Legistes reticulatus* and mosquito fish *Gambusia*), frogs *(Hyla regilla)* and newborn mice. All of the snakes were initially fed fish and occasional frogs. Once the snakes were large enough, newborn mice were fed exclusively. In order to get young snakes to accept newborn mice, the mice were scented by rubbing them against a fish or frog. Young snakes were fed every 2-3 days and adults 1-2 times per week.

All frogs were frozen a minimum of three days prior to feeding to avoid possible trematode infestation (Stoskopf and Hudson 1982). Fish were offered live from forceps or in shallow dishes of water.

Snakes were weighed using a triple beam balance and measurements were made using the squeeze box method (Quinn and Jones 1974). Neonates were weighed and measured within two days of birth.

RESULTS

After a cooling period of three months, male garter snakes were introduced to females in off-exhibit aquaria (F.W.Z.) or in an exhibit cage (D.Z.). Usually, the male immediately began courting the female with copulation occurring within eight hours of the introduction. Courtship and copulation corresponded to that described for other subspecies of *Thamnophis sirtalis* (Garstka et al. 1982; List 1950; Pisani 1976).

Copulatory plugs (Devine, 1975) were evident in the females' vents after copulation (Figure 1). The plugs varied in size and were clear initially and turned to a translucent amber color by the following day. The plugs gradually dissolved within three days of copulation.

During gestation, females were observed basking daily, directly under spotlights placed over their cages. Gravid females fed through most of the gestation period with some females refusing food in the last 2-3 weeks.

Parturition occurred after a gestation period ranging from 79 to 98 days. Weight loss after parturition was recorded for two females. F.W.Z. female A had a mass of 167.7 g 14 days prior to parturition (4 June 1984) and was 114.7 g immediately after giving birth, showing a 31.6% (53.0 g) loss of mass. D.Z. female A had a mass of 200.0 g three days prior to parturition (1 June 1986) and was 139.0 g immediately after birth, showing 30.5% (61.0 g) loss of mass.

All neonates shed immediately after birth and exhibited coloration much duller than

Phylogenetic Relationships of the Lizard Families

ESSAYS COMMEMORATING
CHARLES L. CAMP

Edited by Richard Estes and Gregory Pregill. Using modern analytical methods of phylogenetic systematics, this is the first comprehensive treatment of the relationships among lizard families to appear in over 50 years. In chapters by the leading experts on particular squamate taxa or anatomical systems, it brings together a vast body of information intended both for systematists and for biologists who know the value of interpreting organismal biology and evolution against a historical background. Illustrated with some 180 drawings and photographs. 648 pages. $75.00

Announcing a New Monograph

STUDIES ON CHINESE SALAMANDERS

ERMI ZHAO • QIXIONG HU • YAOMING JIANG • YUHUA YANG*
*Chengdu Institute of Biology, Academia Sinica, and *Sichuan University, Chengdu*

CHINA possesses one of the largest salamander faunas (34 species in 12 genera and three families: Hynobiidae, Cryptobranchidae, and Salamandridae). Included in this number are the primitive hynobiids which are restricted to eastern Asia and the Chinese giant salamander, largest of all living salamanders. This book is the first review in English of the entire Chinese salamander fauna (both mainland and Taiwan) and includes four sections, three of which were published previously in Chinese and which are here translated, corrected, and updated.

STUDIES ON CHINESE TAILED AMPHIBIANS, by Ermi Zhao and Qixiong Hu. A complete classification of Chinese salamanders with key to families and genera, checklist of species, and distribution maps. Adapted from a book published in Chengdu in 1984. This includes an appendix on the chromosomes of *Batrachuperus* by Yuhua Yang and Ermi Zhao.

TAXONOMY AND DISTRIBUTION OF *BATRACHUPERUS*, by Ermi Zhao and Yaoming Jiang. A detailed review of these hynobiids including a key to species, adapted from *Research on the Qing-Zang Plateau*, published in Kunming, 1983.

TAXONOMY AND EVOLUTION OF HYNOBIIDAE IN WESTERN CHINA, WITH A DESCRIPTION OF A NEW GENUS, by Ermi Zhao and Qixiong Hu. Covers the status of *Ranodon wushanensis, Hynobius* in western China, the evolutionary relationships of Chinese hynobiids, and the new genus *Liua*, adapted from *Acta Herpetologica Sinica*, Chengdu, 1983.

A CHECKLIST OF CHINESE SALAMANDERS, WITH COMMENTS ON RECENTLY-DESCRIBED TAXA, by Ermi Zhao. A completely new section, reviewing in detail all newly-described genera (3) and species (9) since 1982 with full references, plus a checklist of all species.

David B. Wake of the University of California at Berkeley has supervised the translations, performed by Eileen Liching Tang of the same institution. The book consists of 80 pages, with 16 figures, 19 tables, and seven plates including *ten photographs of salamanders and their habitats in full color*. The book is clothbound and measures 7 by 10 inches (18 x 25.5 cm).

PRICES AND ORDERING INSTRUCTIONS

Copies of the book can be obtained from the Publications Secretary, c/o Douglas H. Taylor, Department of Zoology, Miami University, Oxford, Ohio 45056, USA. Please make checks payable to "SSAR"; receipt sent on request only. Prices include shipping charges (book rate) within USA; all overseas orders will be billed only for the *additional* costs in excess of domestic rates. Publications sent at customer's risk; however, packages can be insured at your cost. Overseas customers must make payment in USA funds, by International Money Order, or by MasterCard or VISA (in which case account number and expiration date must be provided).

CLOTHBOUND BOOK, WITH TEN COLOR PHOTOGRAPHS (ISBN 0-916984-18-4):

- Prepublication price to SSAR members if ordered before 1 September 1988.....$10
- Price to Institutions, Non-members, and to all purchasers after 1 September 1988.....$12

The Society publishes *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Herpetological Circulars, Contributions to Herpetology* (monographs), and *Catalogue of American Amphibians and Reptiles*. Pricelist available from Dr. Taylor who can also send information about Society membership on request.

that of the adult snakes. Neonates began feeding within three days after birth.

Reproductive data for six captive breedings of *T. s. tetrataenia* are summarized in Table 1. F.W.Z. female B was captive raised (from F.W.Z. 4 June 1984 brood) and then bred to her mother's sibling (F.W.Z. male B) on 11 March 1986. Time to sexual maturity for this female was one year 273 days. No deleterious effects from inbreeding were noted in the resulting young.

Some mortality did occur in rearing neonates at both zoos. Two neonates from the F.W.Z. 1984 brood died at 17 and 46 days of age respectively, due to a suspected ameoba infestation. The source of the infestation is unknown. Another neonate from this brood was born with its spine kinked posteriorly and was euthanized. Three neonates of the D.Z. 1985 brood died from a heavy visceral pentostomid *(Sebekia oxycephala)* migration between 3 October 1985 and 23 October 1985. The pentostomids came from the locally seined live mosquito fish *(Gambusia)* used as food (Corkum, pers. comm.). All of the remaining young were given pryanthal pamoate (Strongid-T, Pfizer Inc.) orally at a dosage of 25 mg/kg body mass followed 10-14 days later by subcutaneous injection or oral administration of Ivermectin (M.S.D. Agvet, Inc.) at a dosage of 0.2 mg/kg body mass. Further mortality did not occur and mosquito fish *(Gambusia* sp.) have since been eliminated from the snakes' diet.

Other medical problems encountered were protozoan infestations in the adult snakes. Routine fecal examination prior to the hibernation period revealed flagellated protozoans (F.W.Z.) and ameoba infestation (D.Z.). Treatment consisted of oral administration of metronidazole-di-iodohydroxiquinoline (Flaganase 400, Liomout Labs.) at a dosage of 200 mg/kg body mass repeated in 14 days.

DISCUSSION

Due to the small range and protected status of *T. s. tetrataenia*, published information on reproduction of this subspecies is scant. Barry (1978) mentions a litter of 25 young from a wild-caught female donated to the Steinhart Aquarium.

Because of the endangered status of *T. s. tetrataenia* and our successful captive breeding of the race, supplementation of depleted wild stocks may appear to be a desirable management method. However, Barry (1978) stated the release of captive-born stock at this time appears to be unnecessary and that the risks (e.g., introduction of unfavorable genotypes) outweigh the benefits. He believed that habitat protection, creation of reserves, and enforcement of protective laws would preserve the subspecies and that captive breeding should be a last resort measure.

The original confiscated *T. s. tetrataenia* received by us were not returned to the wild for fear of genetic contamination by *T. s. infernalis* housed with them prior to the confiscation.

While release of progeny from these snakes is not desirable or necessary at this time, the offspring do have educational value. Barry (1978) stated that the lack of public awareness of the plight of the subspecies is a management problem. Progeny of the snakes in our collections have been and will continue to be sent to other zoos and educational institu-

tions. Through the use of zoo graphics, publications, etc., captive *T. s. tetrataenia* will contribute towards the goal of public awareness of the need to protect the remaining wild populations and their habitat.

ACKNOWLEDGMENTS

We wish to thank the staffs of the Departments of Herpetology at the Dallas and Forth Worth Zoos for their support and assistance. James B. Murphy, Dr. Neil B. Ford, and Dr. Bonnie L. Raphael kindly reviewed the original draft and offered many helpful suggestions. Special thanks to Ken McCloud for his encouragement and for making the specimens available to us. We also thank Dr. Kenneth C. Corkum for the identification of the pentostomids. Many thanks go to Wanda Weaver for typing several drafts of this paper.

LIFE HISTORY NOTES

LIFE HISTORY NOTES is analagous to Geographic Distribution. Individual notes are to concern only one species, and authors are requested to choose a keyword which ***BEST*** describes the nature of their note (e.g., Reproduction, Coloration, Morphology, etc.). Figures are permissable to illustrate any data, but should ***REPLACE*** words rather than embellish them. Reports of clutch or litter size should include snout-vent and total lengths of females. The section's intent is to convey information rather than demonstrate prose. Articles will still be reviewed and edited prior to acceptance.

General format is: SCIENTIFIC NAME in caps (Common Name in parentheses—use Collins, *et al.* 1982. STANDARD COMMON AND CURRENT SCIENTIFIC NAMES FOR NORTH AMERICAN AMPHIBIANS AND REPTILES, for North American forms). KEYWORD in caps. Data on the animal (references may be *briefly* cited in text — ***DO NOT*** include complete literature reviews — use summary articles whereever possible). Place of deposition or intended deposition of specimen(s) and catalog number(s). Then, skip a line and close with Submitted by (Name(s) in caps) (addresses). Recommended citation for items appearing in this section is as for Geographic Distribution notes.

Please submit Life History Notes in the standard format directly to the ***SECTION EDITOR*** to avoid delays in publication: Peter J. Tolson, Toledo Zoological Gardens, 2700 Broadway, Toledo, Ohio 43609, USA.

ANURA

RANA AREOLATA AESOPUS (Florida Gopher Frog). **MOVEMENT.** An adult female *Rana areolata aesopus* (84 mm SVL), marked at the Breezeway Pond on the Katharine Ordway Preserve/Swisher Memorial Sanctuary, 4 km E of Melrose, Putnam County, Florida, on 30 March 1987, was caught in a Sherman live trap set at the mouth of an active gopher tortoise burrow on 26 July 1987. The recapture occurred 2.0 km WSW of the Breezeway breeding pond on a disturbed longleaf pine-turkey oak site dominated by planted slash pine. We believe this to be the first documented observation of a long-distance movement for this frog. Carr (1940, Herpetology of Florida, p. 64) states these frogs ". . . travel some distance to congregate at widely separated ponds, since I have found them a mile (1.6 km) from water."

Submitted by **RICHARD FRANZ,** Florida State Museum, University of Florida, Gainesville, Florida, 32611, **C. KENNETH DODD JR.,** National Ecology Center, U.S. Fish and Wildlife Service, 412 N.E. 16th Avenue, Rm. 250, Gainesville, Florida 32609, and **CHERI JONES,** Department of Zoology, University of Florida, Gainesville, Florida 32611, USA. ●

RANA LIVIDA (Green Cascade Frog). **DENSITY.** In South China this brilliantly colored species is "most often seen clinging to rocks or in crevices and is adept at this due to its enlarged toe disks" (Karsen, Lau, and Bogadek 1986. Hong Kong Amphibians and Reptiles, Urban Council, Hong Kong: 136 pp). We located an accessible and seemingly dense population at Fei Shue Tang (Waterfall Pool), *ca.* 70 m within the Man-and-Biosphere Reserve, Dinghushan, Guangdong Province, China (Lazell and Liao 1986. Acta Herp. Sinica 5(1): 70-71). We conducted repeated mark-recapture censuses between 27 April and 26 May in 1986 and 1987. The frogs were actively breeding at this time; all individuals appeared sexually mature. Twenty-four males measured 44-52 mm SVL ($\bar{X}$ = 49). Nine females measured 85-95 mm SVL ($\bar{X}$ = 89). One female, 92 mm SVL, was caught in both years. Travel distance between recaptures was 2.75-37.0 m ($\bar{X}$ = 12.3). There was no significant difference between average male and female travel distances: 14.3 and 10.25 m respectively. We used average travel distance to calculate the size of the area sampled as 0.259 ha. We estimate the population to be 32 individuals with 95% confidence limits 20-101. Our point estimators were not significantly different in 1986 and 1987: 34 and 29 respectively. Density is approximately 124 *Rana lividia* per hectare. Our work was supported by the Conservation Agency and Earthwatch.

CAUDATA

AMBYSTOMA TIGRINUM (Tiger Salamander). **MIGRATION.** A migration of recently metamorphosed tiger salamanders was observed beginning 21 July 1986. Movements were witnessed on the three following mornings, but the intensity of migration appeared to decrease steadily after the initial peak on the 21st. The animals were found moving primarily southward across US Hwy 86 in Dickinson Co., Iowa (R37W/T99N s.36) and a few (<10) were found moving southeasterly across the N-S blacktop connecting Hwy 86 with the Terrace Park road. In 1987, a southward migration of newly metamorphosed individuals from the same population again

began on the morning of July 21. No evidence of movement to the north was seen in either year. The salamanders apparently emerged from a small farm pond located 600 m directly north of the highway. During both years the pond was surrounded by cultivated agricultural land. Roads in the area of the observed migration were traveled regularly on mornings before and after the migration, but no movement was seen prior to July 21 during either season.

In 1986, ca. 25 salamanders were observed crossing a 400 m length of Hwy 86 between 0830 and 0900 h on the first morning. Numerous road-killed individuals suggested that more extensive movements probably occurred early in the morning. There were only two road kills and one live salamander observed on the N-S road. Fewer live salamanders and road kills were seen before 1000 h on the following three mornings. Heavy rains preceded the initial observed migration and substrates were found to be cool and damp on the following mornings.

The migrating population appeared to be smaller in 1987 as reflected by fewer road kills (12) along the same 400 m stretch of Hwy 86. As in the previous year, heavy rain fell during the early morning hours on the day of migration in 1987.

Although experimental evidence is lacking to distinguish the causal relationship of either time of year or rainfall on the migratory movements, it is nevertheless interesting to note that the same population consistently initiated movement on July 21 during the two years of monitoring and that the movements occurred following heavy rainfall.

Submitted by **BLAINE P. BIEDERMANN**, Department of Zoology, University of Tennessee, Knoxville, Tennessee 37996-0810, USA. ●

GYRINOPHILUS PORPHYRITICUS (Spring Salamander). **MAXIMUM SIZE.** On 17 May 1986 an exceptionally large *Gyrinophilus porphyriticus* was collected by Edgar L. Breland just inside the entrance to Bryant's Corkscrew Cave in Blount Co., Alabama (T13S, R3W, Sec. 22). SVL = 137 mm; TL = 232 mm. This specimen, verified by William A. Cox, exceeds the record TL of 219 mm listed for the species by Conant (1975. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, Houghton Mifflin Co., Boston). Subspecific designation was not assigned, as Mount (1975. The Reptiles and Amphibians of Alabama, Auburn Univ. Agricultural Experiment Station, Auburn) noted that all Alabama populations are considered intergradient between subspecies *porphyriticus* and *dunni*. The new record specimen is deposited in the University of Alabama at Birmingham Vertebrate Museum (VM-UAB 0385).

Submitted by **KEN R. MARION,** Biology Department, University of Alabama at Birmingham, Birmingham, Alabama 35294, and **JAMES LAMB,** Red Mountain Museum, Birmingham, Alabama 35205, USA ●

PLETHODON VEHICULUM (Western Redbacked Salamander). **PREDATION.** Though *P. vehiculum* is believed to be preyed upon by garter snakes (genus *Thamnophis*), apparently no documentation of such predation exists (Nussbaum, Brodie and Storm 1983. Amphibians and Reptiles of the Pacific Northwest. University Press of Idaho. Moscow. 322 pp.). On 4 June 1984, a foraging adult *Thamnophis sirtalis* (SVL 414 mm) was collected in dense coniferous forest on Cape Alava Trail, ca. 3.2 km W of Ozette Ranger Station, just W of Ahlstrom's Prairie (T31N, R16W, Sec. 26), Olympic National Park, Clallam Co., WA. The stomach of this specimen contained the partially digested remains of two adult *P. vehiculum* (orange phase) and the partial vertebral column of an unidentified salamander. Vouchers, including the snake, are deposited in the University of Washington Burke Museum (UWBM 104, 109, 110).

SAURIA

SCELOPORUS UNDULATUS CONSOBRINUS (Southern Prairie Lizard). **COLORATION.** An undescribed color pattern is typical of males in a population occupying the sand sheet region in Kenedy County, Texas, where lizards were collected on oaks along U.S. 77 between Sarita and Armstrong and on U.S. 281 between Falfurrias and Encino. In adult males, the side of the head is bright yellow, as is all of the ventral neck surface anterior to the blue throat patches. Females appear to lack this yellow coloration. Otherwise, the color pattern is typical for *S. u. consobrinus*. The yellow head coloration is a potential chromatic social stimulus.

SCELOPORUS UNDULATUS ELONGATUS (Eastern Fence Lizard, North Plateau Lizard). **BEHAVIOR.** We recently observed an extraordinarily glutted individual of this species. The lizard was captured on 5 June 1987 in Jones Canyon in Dinosaur National Monument. Although the temperature was warm (ca. 29° C) with sunny weather, this male, in apparently good condition, was not as mobile nor agile as is typical of the species, being unusually easy to capture by hand. The width of this individual's abdomen was about one-third of its SVL and was bulging and slightly lumpy due to engorged food. These food items could be felt while holding the lizard. We could not find a similar instance in the literature where an individual of this species had engorged itself to such an extent that its ability to escape predation was significantly affected. The diet of this species is known to include a variety of insects, including Orthopterans (Hammerson, G.A. 1982. Amphibians and Reptiles in Colorado. Colo. Div. Wildlife, DOW-M-1-27-82. 131 pp.). This individual probably had been feeding on Mormon crickets (*Anabrus simplex*), which are currently experiencing a population explosion in the area. The population of Mormon crickets at the site where the lizard was caught was extremely dense, essentially forming a moving dark mass on the ground and low lying rocks such as the one on which the lizard was captured. That these large crickets formed a readily available, easy-to-capture prey base only conservatively describes the situation.

LIVE CRICKETS

. . .an excellent food source for most amphibians and reptiles.

With a dryweight analysis of 60% protein, 35% lipid and 5% carbohydrate, it is obvious why crickets are considered a valuable nutritional food source for amphibians and reptiles.

Fluker's Cricket Farm offers crickets in a variety of sizes and stages, from 1 day (1/8") to 6 weeks old (1") at a cost of $12/thousand (or a minimum order of 500 for $9.00) plus postage. Shipments are made year-round with guaranteed live delivery.

Fluker's Cricket Farm offers fine, healthy specimens. Our company takes pride in personal service, striving for individual attention and efficient shipping. We would appreciate an opportunity to serve you.

Phone (504) 343-7035.

Fluker's Cricket Farm, Inc.

SERPENTES

CROTALUS ATROX, (Western Diamondback Rattlesnake). **HUNTING BEHAVIOR.** Several field observations of one specimen of *Crotalus atrox* have shown repetitive behavior and close association with a single dwelling place. The described behavior took place at the fringe of the Aden Lava Flow in southern New Mexico. The individual studied has been observed inhabiting a crevice in a lava cliff ca. 3 m high. On 17 June and on several other dates during summer 1987 at ca. one and two week intervals, the rattlesnake emerged from the crevice, paused at the mouth for ca. 10 min and then crawled from the shelter approximately 2 m along the base of the ledge to a circular area on the ground 35 cm in diameter which has been denuded of grass and detritus through constant use. The bare patch is tangential to a well-used track used by pack rats and kangaroo rats which abound in the flow.

The snake approached the bare patch, drew the head slightly past it and then brought the tail to the center of the bare patch, carefully covering the rattle with the next layer, then forming an outer coil with the thickest portion of the body and then leaving the anterior part of body and head resting at the top. Once this coil was formed, the snake extended head and neck ca. 15 cm further along the ledge as though preparing to proceed further but then the head was pulled back after sensing the ground and the behavior was repeated at 90° counterclockwise from the first sensing extension. My observation point was 3 m distant from the snake. It should be noted that the rattlesnake did not attempt to explore the ledge behind its coil or to re-examine the path it had assayed to get to the hunting spot. Once the other approaches to its coil were explored it settled and did not rouse itself to rattle even when approached carefully within 50 cm for a closeup photograph. Several encounters with *C. atrox* indicate that when hunting the snake may consistently lie on its own rattle, presumably to avoid giving its position away when prey approaches.

ELAPHE GUTTATA (Corn Snake). **REPRODUCTION.** Fitch (1970. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 52:1-247) indicated the largest reported corn snake clutch to be 21 eggs. A large female (137.5 cm SVL, 157.0 cm TL) was collected 25 Feb. 1987, 2.5 km NE of Carrabelle, Franklin Co., Fla. It was maintained in captivity and observed by one of us (DWJ) in copulation with a smaller male collected from the same locality. Oviposition began on 2 June 1987, when 29 eggs were deposited. Egg laying continued through 5 June 1987, and 11 additional eggs were deposited, bringing the total clutch to 40 eggs. The reason(s) for the extended period of egg deposition is unknown, but may have been a result of the unusually large number of eggs. The eggs were weighed and measured within 24 h of oviposition; $\bar{X} = 3.11 \pm 0.20$ cm length, 2.10 ± 0.10 cm width, and 8.35 ± 0.81 g mass. The eggs were incubated in damp vermiculite. The last six eggs laid were fully yolked but infertile. This is in contrast to only one infertile egg from the 29 eggs deposited the initial day of oviposition.

ERPETON TENTACULATUM (Tentacled Snake). **REPRODUCTION.** Little information is available on tentacled snake reproduction. Seven *E. tentaculatum* litters have been born at the New York Zoological Park since 1970. Births were noted from early July to early October and litter size ranged from 5-12 young (X = 7.9). Parturition dates, litter size, SVL, TL and mass data are indicated in Table 1. SVL, TL, and mass were not recorded for litters A and B.

First ecdysis occurred 1-3 days postpartum. The young *Erpeton* began accepting 20-25mm long goldfish one day after birth.

Litters B - G were born to a group of six females (ranging from 36.0-48.0 cm SVL/48.5-66.0 cm TL with a mass variationof 69.2-148.0 g) maintained with a single adult male 34.5 cm SVL/49.0 cm TL; mass 57.7 g). All were wild caught and imported form Thailand in 1983 and 1984. On 17 February 1984, 1.5 animals were introduced into a 730 l aquarium half-filled with water. A sixth female was added to the group 27 September 1984. Numerous branches, which extended from the gravel substrate to above the water surface, were provided for basking and subsurface perching. A 150-watt incandescent spot bulb, directed toward the center of the basking area, was positioned 50 cm above the water surface. Water temperature was maintained at a relatively constant year-round temperature of 26-27° C. Water was circulated through a subgravel filter at 6.0 gpm (22.7 lpm) via a March MDX-3, 1/25 HP, magnetic drive pump. The snakes were fed ad libitum, fifty 20-35 mm long goldfish/week.

Courtship behavior was observed only on 24 February 1985. The male died 12 March 1986. It is interesting to note that all 1986 broods were born well after the male's death; the last occurred 29 weeks after that event.

***GEOPHIS* SP. PREDATION.** There are numerous records of predation on small snakes by large invertebrates, however this account may add both a new predator and new prey species. The vinegaroon or whip scorpion (*Mastigoproctus giganteus*) is a common and easily recognized inhabitant of the southern United States and Mexico. It is known to take a wide variety of arthropod prey and occasionally small frogs (Cloudsley-Thompson. Spiders, Scorpions, Centipedes and Mites, Pergamon Press, Oxford, p. 147). On 7 August 1987 we found a vinegaroon 35 mm body length under a stone on a hillside 12 km NE Xicotepec de Juarez, Puebla, Mexico. It was in the act of eating a very small tricolor snake about 90 mm in length. The snake was dead and about a quarter of its midbody portion reduced to pulp (Fig. 1). On the basis of color, pattern, and geographic locality, it is tentatively identified as *Geophis semidoliatus* (Dumeril, Bibron & Dumeril).

HETERODON NASICUS KENNERLYI (Mexican Hognose Snake). **COLORATION.** An amelanistic *Heterodon platyrhinos* was described by Dyrkacz (1981. SSAR Herp. Circ. No. 11). On 8 May 85 an amelanistic female *Heterodon nasicus* was collected by Alfredo Gonzalez on the high school grounds of the Universidad Autonoma de Nuevo Leon (located at NE of Ejido Esmeralda; ca. 26 km from Gomez Palacio, Durango, Mexico). On 15 May the specimen was brought to the Museo de Historia Natural by Prof. Fernando Jimenez G. (MHN-0136). On arrival the snake's mass = 12.45 g, SVL = 112 mm, and TL = 139 mm. Dorsal blotches of the snake were creamy white with white interstices. The venter was yellow and the eyes were reddish.

The specimen was maintained in captivity and began feeding on tadpoles of *Gastrophryne olivacea* on 17 May after initially refusing to eat. It continued feeding on two tadpoles ($\bar{X}$ mass = 0.94 g) twice weekly. The snake eventually began feeding on juvenile mice (2-3 each week, $\bar{X}$ mass = 10.45 g). Upon its death it will be deposited in the Museum's herpetological collection. I wish to thank Director Luis Galan Wong for providing materials to maintain the snake in captivity and support for future studies.

LIASIS PAPUANUS (Papuan Olive Python). **FEEDING.** The Southern Trans-Fly region of the Western Province of Papua New Guinea is a large low-lying area dominated by extensive *Eucalyptus alba* savannas, tree and palm swamp woodlands and monsoon forest. The vegetation of the coastal and estuarine fringes consists largely of *Nipa* palm and dense mangrove swamps. The entire region receives between 40 and 100 inches of rainfall annually, a relatively low precipitation level for Papua New Guinea. Numerous rivers flow into the Fly estuary and delta to the east and the Torres Strait to the south. The area boasts an impressive herpetofauna comprising New Guinea endemics, northern Australian invaders and introductions and representatives of Oriental and Pacific taxa, including six of New Guinea's eight pythons.

The Trans-Fly region contains numerous riverine villages and many of the people survive entirely by hunting and fishing and by harvesting sago, potatoes and various fruits. The method of fishing largely consists of the setting of gill nets on a series of imbedded stakes along the slow stretches of the river, parallel to the flow. On occasion large pythons become entangled in these nets as they swim across the rivers. The author was called upon to free an eight foot D'Albert's python, *Liasis albertisi*, from such a net on the Binaturi River, near the village of Kunini, and the next day a second python, a drowned Papuan python, *Liasis papuanus*, was brought into camp following its discovery in another gill net on the same river.

The alternating bulges of this python's last meal aroused suspicion and further examination revealed a partially digested Amethystine python, *Morelia amethistinus*. The Papuan python measured 1932 mm and the more slenderly built amethystine python approximately the same, as near as could be established due to *rigor mortis*. Since the second python had been swallowed headfirst and no other prey item was present in the stomach of the *Liasis* it would appear that this episode represents a case of python ophiophagy. The gut of the Papuan python also contained a large population of nematode worms.

Pythons are not normally known to eat snakes with the exception of the Northern Australian black-headed python, *Aspidites melanocephalus*. The inclusion of a large snake in the diet of the Papuan python, a species thought to prey largely upon mammals ranging in size from marsupial mice, (pers. obs.), to wallabies, (McDowell S.B. 1975. A catalogue of the Snakes of New Guinea and the Solomons, with Special Reference to Those in the Bernice P. Bishop Museum. Part II. Anilioidea and Pythoninae. *J. Herp.*, *9*(1):1-79. Parker F. 1982. *The Snakes of Western Province.* Wildlife in Papua New Guinea No. 82/1. Div. Wildlife, Dept. Lands & Environment.) and birds, (McDowell op. cit), and possibly lizards, constitutes an interesting observation. This may be a potential problem associated with their maintenance in captivity. The author has been unable to locate any further records of instances of python ophiophagy in New Guinea.

The collection of these two specimens took place on 20 June 1986 during a 3½ month herpetological project which the author was conducting as part of the scientific work on the Papua New Guinea phase of Operation Raleigh. Both specimens were preserved and have been deposited in the collection of the British Museum (Natural History): *Liasis papuanus* (BM 1986, 1175); *Morelia amethistinus* (BM 1986, 1176).

For invaluable assistance in the field during the 3½ months duration of the project, thanks to the Venturers of Operation Raleigh; also the University of Papua New Guinea, (John Pernetta, Peter Lambley, John Hillary); National Museum of Papua New Guinea, (Jim Menzies); Fred Parker and Division of Environment and Conservation, (Karol Kisokau).

MASTICOPHIS FLAGELLUM FULIGINOSUS (Whipsnake). **PREDATION.** Many snakes are known to include birds and their eggs as part of their diet (Porter 1972. Herpetology. W.B. Saunders Co.), but usually there is little direct evidence of predation (G.T. Austin et al. 1972. Condor 74:492). We report an instance of coachwhip snake (*Masticophis flagellum fuliginosus*) predation on an adult black-throated sparrow (*Amphispiza bilineata*).

One of us (DW) observed the incident on 6 July 1981 in the Catavina region of Baja California, Mexico. The site is 9 km NW Rancho Santa Ines, latitude 29° 46'N, longitude 114° 46'W, elevation 550 m. The area is characterized by granite boulder fields, sandy soil, and scattered perennial vegetation including creosote bush (*Larrea tridentata*), ocotillo (*Fouquieria splendens*), boojum (*Idria columnaris*), elephant tree (*Pachycormus discolor*), mesquite (*Prosopis juliflora*), *Ambrosia dumosa, A. chenopodifolia* and a variety of cacti.

At ca. 1430 h (air temperature 34.5° C, relative humidity 14%), a coachwhip snake was observed entering a small pile of leaves, twigs, and rocks at the base of an elephant tree at about seven m distant from DW. At ca. 1500 h (air temperature 35° C, relative humidity 15%), three adult male black-throated sparrows alighted on branches of the elephant tree. All remained on branches about 1.5 m from the ground for several minutes at which point one flew down to a branch about 0.4 m from the ground surface. He was struck immediately by the whipsnake and pulled to the ground in the snake's jaws. The snake had apparently been lying in wait among the dead leaves and branches on the ground. As DW and two fellow expeditioners approached to investigate, the snake released the bird which escaped, seemingly unharmed. The black-throated sparrow and coachwhip are both common at this site. We do not know the impact of coachwhip predation on the black-throated sparrow or other bird species, but it may be an important factor in the survival of adults and nestlings alike.

Stebbins (1954. Amphibians and reptiles of Western North America, McGraw-Hill) notes

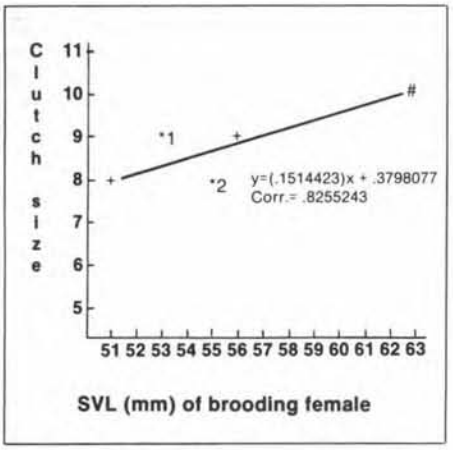
that the food of the common whipsnake includes birds. Austin et al. (1972. Condor 74:492) reported whipsnake predation on cactus wrens in Arizona. Finch (1981. Condor 83:389) reported *M. flagellum* as a predator of nestling Abert's towhees (*Pipilo aberti*) and a nestling brown-headed cowbird (*Molothrus ater*). The black-throated sparrow has apparently not been previously noted as a prey item of the whipsnake.



This research was funded in part by grants from EARTHWATCH and The Center for Field Research of Belmont, Massachusetts to WHC. We thank Paul E. Blom, Eric Yensen, and other members of the expedition for assistance in the field.

The coachwhip was collected and the specimen has been deposited in the Museum of Natural History, College of Idaho (CIDA 66).

ERRATUM

The graph points on Figure 1 of Life History Note *Ensatina escholtzii oregonensis* (Oregon ensatina) Reproduction (*Herp. Review* 17(4):89. 1986), by Bradford R. Norman, were unfortunately placed in the wrong positions during typesetting. The corrected graph appears below. The editor regrets the error.

MORELIA SPILOTES VARIEGATA (Carpet Python). **MALE COMBAT.** On 15 February 1987 I observed vigorous combat behavior between two adult male *M. s. variegata* in my laboratory. The contest occurred when both males were removed from their respective enclosures and placed together on the floor during manipulation of the breeding colony. Both males were equal in size (1.9 m). They had been separated from one another for several months previous to the encounter on the floor. One of the males involved, identified as LV1, had been housed with another male, identified as TGR2, without incident. The involved males had been very active, constantly prowling their enclosures for several weeks and both were off feed. LV1 had copulated with one of the females in the breeding colony on 30 November 1986 and 10 February 1987, the latter breeding occurring when the female was apparently gravid. The other male involved, identified as CR3, had not yet copulated with any females in the colony.

The combat ritual consisted of the pythons rearing their heads and foreparts of their bodies to a height of up to 46 cm and vigorously intertwining their bodies and tails in a corkscrew fashion while each attempted to press the other's head to the ground. Several times they violently slammed one another to the ground from the reared position. During the contest, which lasted 29 minutes, both males were breathing heavily to the point that their throats were puffing out considerably upon exhaling. At no time during the combat ritual did either male bite, or attempt to bite, the other. The contest ended when LV1 very rapidly crawled away from the area. The other male, CR3, started to give chase then abruptly turned and returned to the contest site. With head reared up to 50 cm above the ground he circled the contest site for seven minutes before crawling away. Another male identified as TGR2 was placed near CR3 but neither showed interest in the other. CR3 was then placed with three different females which were housed separately. He did not initiate courtship with any of them but remained in a very active state, constantly on the prowl. Eight hours later LV1 was again placed on the floor with CR3. CR3 reared his head and approached LV1 but LV1 did not rear his head and, as if in a panic, rapidly crawled away. CR3 remained in the reared position, which was apparently a dominance display, after LV1's retreat.

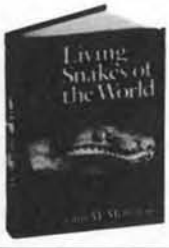
TECHNIQUES

A PHOTOGRAPHIC METHOD FOR QUANTIFYING COLORS

One of the principle difficulties in assessing color morphs, clinal variation in color, and color changes in amphibians and reptiles lies with imprecise means of describing and remembering colors. Nassau (1983) reports several definitions of color from different sources. In all, color is defined in terms of human perception. Verbal descriptions of color leave a great deal to be desired, partly because individuals perceive color differently, and partly because their attempts to assign meaningful words to their perception of the color is futile.

Most attempts to describe color in quantitative terms involve either chemical extraction or visual comparison to standardized color chips. Using extraction methods, pigments are dissolved and the solution analysed with a colorimeter. If the pigments are soluble and if the color is produced by soluble pigment alone, this procedure can provide repeatable, quantitative data. However the color of an amphibian or reptile may be influenced more by nonpigmentary structural colors and the distribution of pigment than by amount, and this method necessitates sacrificing the animal.

The use of color chips is preferred in most cases because it is quick and simple, provides standardized colors and notation for communication with other workers, and permits the researcher to record the combined effect of pigmental and structural colors. The Munsell System is the most widely used in the United States although there are others such as the CIE (Commission Internationale de l'Eclairage) system, or variations on such systems as presented by Palmer (1962).



The parameters of the Munsell system are established by dividing the colors (hues) into 10 equally spaced blocks as determined by a

"standard observer" (Mitchell 1984). The assessment of lightness and darkness (value) and color intensity (chroma) are also defined by normal observers. Mitchell correctly recognizes the strengths of the Munsell system as follows: "This system of color representation is psychological in nature, because the eye of a human observer is the measuring instrument. This is as it should be since the intent is to catalogue and describe what people see." Because of the nature of the Munsell system the value of statistical analysis has some limitations.

In this paper, I describe a procedure that provides for non-invasive color quantification applicable to colors that result from pigment alone, structural factors, or both. It is inexpensive, provides reasonably permanent records and is therefore particularly suited to recording and measuring color changes of individual specimens. It can be calibrated with the color chips of the Munsell system or any other. The only equipment required in addition to a camera is an enlarger equipped with a voltage regulator, and a photographic color analyser (CA). CAs are in common use throughout the photographic industry and may be purchased for as little as $200.

THEORY

It is essential to recognize the components of color to understand how this procedure works. A full range of colors can be produced by mixing only three hues called primary colors. These primaries may be additive or subtractive. Mixing light that is red (R), green (G) and blue (B) (the additive primaries) results in a hue which we perceive as white, or more correctly neutral, since gray, black and white all result from the same mixture of primaries. The subtractive primaries, cyan (C), magenta (M) and yellow (Y) are the complements of the additive primaries. Cyan, composed of equal parts of green and blue, complements red. Magenta results from a combination of red and blue, and complements green. Yellow, a combination of red and green, complements blue. Optical filters of these primaries remove the hue of their complement from light passing through them (e.g. a cyan filter placed in a beam of light removes red from the light in proportion to the strength of the filter). The other subtractive primaries act in equivalent manner to remove their complements.

It is also essential to discriminate among the three properties of color: hue, value and chroma. Hue is determined by the combination of wavelengths of light reflected by an amphibian or reptile, usually reported as its color. Value varies with the proportion of light reflected (whether it is a light or dark animal), and chroma is the intensity of a color, sometimes described as its "saturation" or "brightness." This paper deals only with the assessment of hue. Mitchell (1984) provides a more complete discussion of these properties.

Color film records images using three layers of dye so that three separate images are formed in register. At the time of exposure, each dye layer of the film records the intensity of light reflected from the subject in terms of the subtractive primary colors (i.e. cyan, magenta and yellow). Subsequent projection yields an image with a full range of colors resulting from sequential removal of precise amounts of the primaries from the light beam passing through these layers. It is the function of the CA to measure the density of each layer independently, using a neutral such as gray or white as a reference point. Gray is preferable to white because a standard gray, determined by a central authority (Kodak), is available as a Neutral Gray Card.

EXAMPLE

A specific example from work in progress will help to clarify these relationships. All data from the following discussion are summarized in Table 1. The Cricket Frog (*Acris crepitans*) is a polymorphic species reported by many authors, notably Pyburn (1961) and Gray (1971), to be capable of color changes. The vertebral stripe of a newly captured green-striped morph was described as bright green with a slightly yellow cast. Using the Munsell color chips, a more precise description was possible. It most closely approximates color chip 7.5 GY 5/8 in the Munsell system, a designation which includes evaluation of hue (7.5GY), value (5) and chroma (8). The same specimen was photographed in the field using a Neutral Gray Card background. Subsequent analysis with a CA identified the hue of the vertebral stripe relative to that of the Neutral Gray Card as: OC + 46M - 13Y. These values describe the differences in light transmitted through the gray background image in comparison to the light through the vertebral stripe image. The procedures necessary to arrive at these data will be described below.

Positive values are more easily manipulated than mixed values. It can be assured that one of the primaries is equal to zero and the remaining two positive, by adding gray (equal parts of C, M and Y). This addition does not alter the hue. In this case, adding 13 units of gray (+13C +13M +13Y) converts the reading to positive values. The result is: 13C + 59M + 0Y. The numbers in these formulas, as read directly from the CA, are 100 times the density of each subtractive primary. Density is defined as the log of (1/proportion of light transmitted). It is now established that light passing through the vertebral stripe image differs from that passing through the Neutral Gray Card image by the removal of 0.13 density units of C and 0.59 density units of M.

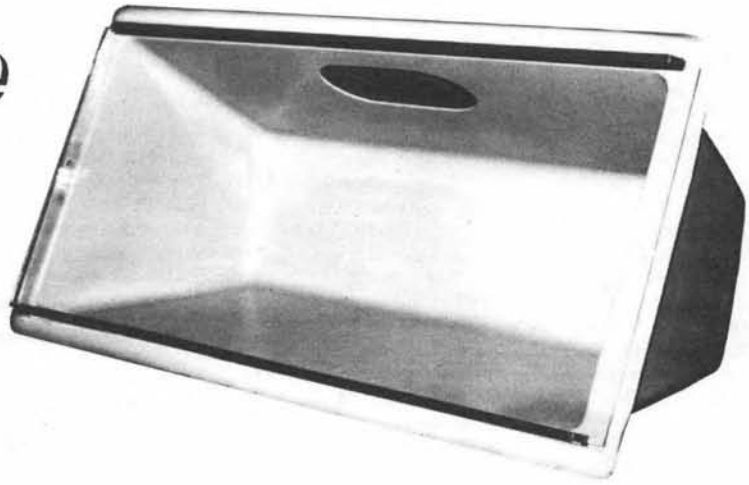
The values 13C + 59M do not seem reasonable descriptors of a green hue, because they are subtractive primaries. We commonly think in terms of additives (which hues might be added to white to change it in a particular way). Therefore, it may be desireable to convert the expression of this hue to its additive components. Subtracting 13C (0.13 density units of cyan) from white light is the equivalent of adding 13R (0.13 density units of red). Thus, with cyan and magenta converted to their additive components, the above reading becomes: 13R + 59G + 0B. Red and green light in equal parts produce yellow, so this hue may be described as green with a yellow cast.

Hues, independent of value and chroma, are precisely described by the ratio of any two primaries. In this case, the hue of the vertebral stripe can be accurately described by a single number, the R/G ratio which is equal to 0.22.

Table 1. Summary of Hue Descriptions from a Cricket Frog.

Visual description	green with yellow cast
Munsell color system	7.5 GY 5/8
Color Analyser	
Subtractive primaries	
- inital reading	0C + 46M - 13Y
- elimination of negatives	13C + 59M + 0Y
Additive primaries	
- equivalent reading	13R + 59G
- Red/Green ratio	.220 R/G

PROCEDURAL DETAILS



The amphibian or reptile under study is photographed on a background of neutral gray. Any neutral gray can be used but the benefits of a standardized gray favor the Kodak Neutral Gray Card. A painted surface may be used so that the necessary wetting associated with handling amphibians will leave the reference gray card unsoiled. If a painted surface is used, the difference in hue between the Neutral Gray Card and the painted card can be recorded by photographing both painted and reference cards on the same slide and measuring the difference with the CA as described below. All sample values can subsequently be adjusted to the standard gray by adding or subtracting the measured amounts. If the Neutral Gray Card is protected with glass, it may be necessary to adjust its hue to the standard gray because the color added by the glass (usually green) will probably be identified by the CA.

Film. A film that produces transparencies, such as Kodachrome or Ektachrome, is most useful. The type of film is not important, though it must be used according to the manufacturer's specifications. Some films are designed for use with daylight or electronic flash, while others are balanced for tungsten illumination. Because of the heat associated with tungsten lights, daylight film used with electronic flash is the recommended combination.

The common observation of faded color images raises the question of permanence. Currently available Kodachrome has the greatest permanence (100 years) without fading, assuming storage in a cool, dark and dry location. This time span is reduced to 30 minutes by projection with conventional 2 x 2 projectors, while the projection life of Ektachrome is 90 minutes (Hammond 1984). Other brands of film are roughly equivalent to Ektachrome, so the researcher need not be concerned about the permanence of the image, unless it is projected for extended periods or subjected to unusual levels of heat or humidity in storage. The use of an enlarger for color analysis, described below, is not equivalent to projection, relative to deterioration of the image.

Exposure. Exposure is not critical. For initial testing, a Kodak Neutral Gray Card can be used according to the enclosed instructions to approximate the correct exposure, but tests should be employed to determine the optimum exposure for the specimens under study. Once established the lighting arrangement should be held constant. In testing with Kodak's Ektachrome 100, overexpo-

Reptile Cages

FOR THE AMATEUR
OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door is inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $33.95
24" Wide, 12-1/4" High, 12-1/2" Deep
250 sq. in. Floor Area, Single Vent

36" Reptile Cage $58.95
36" Wide, 18" High, 19" Deep
580 sq. in. Floor Area, Double Vent

Prices include freight charges and are shipped via UPS. Institutions, zoos and dealers are invited to write on letterhead for quantity prices.

sure or underexposure by a full f-stop did not detectably alter the hue on the transparency. Of the two, overexposure is preferable because the film shifts toward green in parts of the image where exposure of the film is barely above threshold levels, such as in dark regions of the subject or in deep shadows. Therefore, if the hues to be studied are of low value, (e.g. the ground color of *Ambystoma maculatum*) the transparency as a whole may be overexposed so that those hues appear nearer to a middle tone on the transparency. The value will be changed but not the hue. This procedure will eliminate the shift toward green of low exposure areas and provide a broader acceptable range of exposure. Analysis of a series of exposures taken at different f-stops will provide a basis for determining if any correction is necessary.

Equipment for Color Analysis. The transparency is placed in the enlarger and an image of desired size projected onto the baseboard. Any enlarger of reasonable quality will do, but it must be equipped with a voltage regulator, so that fluctuations in line voltage do not alter the color of the light source. There are several color analysers on the market; Omega and Beseler are the most popular brands. They come with a variety of capabilities, of which only the digital read-out is recommended, because it is quicker and probably more accurate than reading the scale of a meter behind a needle. Most CAs are equipped with a probe that rests on the easel and permits analysis of a small portion of the enlarged image, usually a 3 mm to 5 mm disk. This corresponds to an area on the specimen which is highly variable depending on the magnification of the image on the film and in the enlarger. Assessment of subjects 100 micrometers in diameter or less is easily accomplished.

Using the CA. Operation of the CA requires that a reference gray be defined. This is the function of the gray card in the background. It is essential that the image of the subject and of the gray card be subject to the same sources of variation (film type, emulsion number, processing variation, etc.) so that these variables are cancelled. To accomplish this, CA is zeroed with the probe on the image of the gray card. When the probe is moved to the part of the image under investigation, the CA will display the difference between gray and that hue in terms of densities of cyan, magenta, and yellow, one of which will eventually be eliminated.

Recording changes that occur in a single individual requires evaluating the same surface area each time. This can be assured by tracing the projected image on paper or by marking registration points (such as the eyes, lip line and posterior width of the torso). Either will provide permanent records to be filed with the transparencies. It may be desireable to neutralize the impact of small irregularities in pigmentation (scars, freckles, warts, scale boundaries, etc.) if they are not resolved without magnification and hence are not part of the image presented to an observer. To neutralize these irregularities, the image may be thrown slightly out of focus so that they contribute their hue to the general appearance in proportion to their surface area, but do not dominate a particular reading. Alternatively, one could run transects through the image and take readings at any number of points along the line.

Consult Mitchell (1984) for additional information on colors and color sensitometry at a general level. The Kodak Data Books (Anonymous 1974) are also very informative.

A METHOD OF LIVE-TRAPPING WARY CROCODILES

Fifteen of the 21 presently recognized species of crocodilians are endangered (U.S. F.W.S., 1984). This status is a result of both extensive habitat destruction and intensive hunting practices. Managers of populations of endangered species have the difficult task of studying small numbers of wary individuals in large, remote and often inaccessible areas. For example, our experience is that the few remaining adult American crocodiles (*Crocodylus acutus*) in southern Florida are often difficult, and frequently impossible, to approach closely.

Several papers have described methods for direct capture of crocodilians (Chabreck 1963; Jones 1965; Joanen and Perry 1971; Webb and Messel 1977). Murphy and Fendley (1975; trap boards) and Webb and Messel (1977; rope nets) developed live-trapping methods for crocodilians that proved particularly successful with wary, difficult-to-approach individuals. We found two disadvantages to using these techniques: (1) The equipment is bulky, thus limiting the number of traps that can be carried to remote areas; and (2) they require bait. The habits and low numbers of American crocodiles in southern Florida generally mean that their occurrence at any trap site is infrequent. In addition, the bait may attract other predators. Blue crabs (*Callinectes* spp.) and black and turkey vultures (*Coragyps atratus* and *Cathartes aura*) are common and have consumed bait within 48 h of a trap being set. Another disadvantage of trap boards set on trails is that crocodiles easily avoid them. Here we describe a simple, baitless trap for capturing crocodilians.

The trap configuration consists of a #3 Klef-

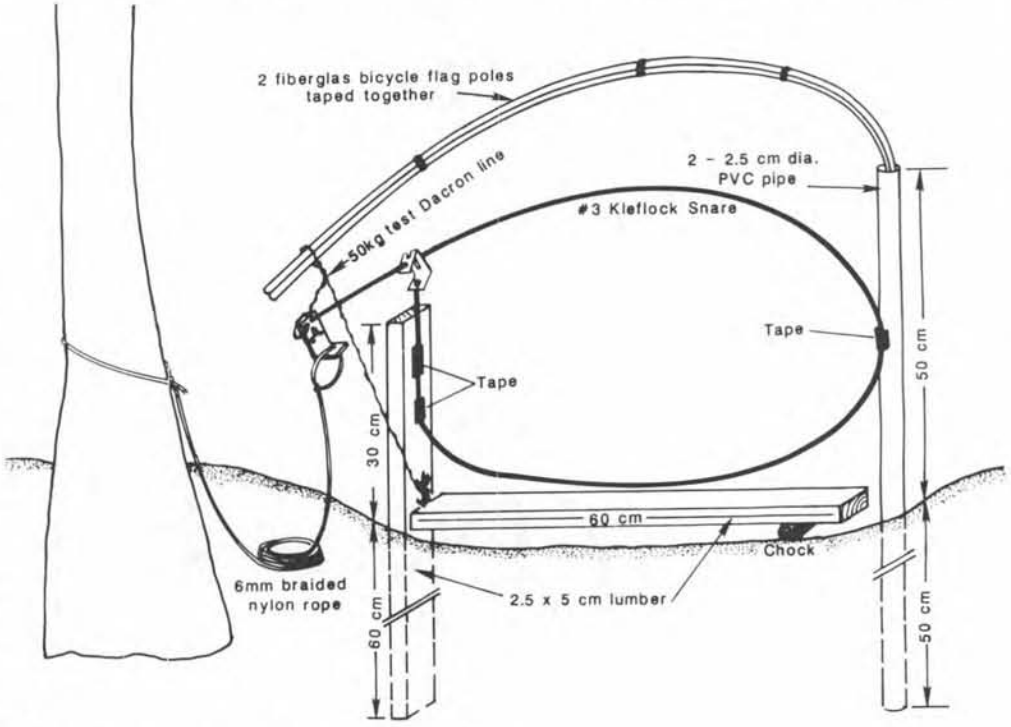

Figure 1. Configuration of crocodilian trail trap.

lock wire noose (Woodstream Corp., Lititz, PA), trigger and spring pole (Fig. 1). The noose is set in a natural narrowing of an active trail between vegetation or where a crawl emerges from the water. The noose is held in place by forked sticks or is lightly taped to the trigger arm and spring-pole support. The snare is anchored to either a stout tree or an iron reinforcing bar driven into the ground, or is attached to a float with 6 mm diameter braided nylon rope of sufficient length to allow the crocodile access to water. We found that two flexible fiberglass bicycle flag poles taped firmly together were the most effective for springing the noose. The spring pole, supported in PVC pipe (2 to 2.5 cm diam., 1 m length) driven into the substrate to approximately half its length, is attached simultaneously to the noose and trigger using 50 kg test dacron trolling line (Fig. 2). The dacron trigger attachment is placed on the flathead nail between the two horseshoe nails and the tension adjusted so that only a slight pressure on the treadle is needed to release the spring-pole. The treadle is depressed by the crocodile's chest, after the head passes through the noose. The noose is usually set partly, or fully, between the fore and hind legs. Traps should be checked at least once a day, preferably by mid-morning to avoid exposing the animal to extreme temperatures.

Seven of 15 adult crocodiles captured in Everglades National Park (ENP) and all (four) of the adult crocodiles captured at Florida Power and Light Company's Turkey Point power plant site (TP) were trapped using this method. Of the 11, 10 were females (seven from ENP associated with particular nests) ranging in size from 2.27 m, 47.6 kg to 3.08 m, 95.4 kg. The one male captured (at TP) was 3.5 m, 215 kg. Five of the 11 adult crocodiles trapped were recaptured using the same method.

One trap was set on each active trail in an area where we wished to capture crocodiles. For example, at nest sites in Everglades National Park we would set one or two traps on the trails that approached the nest from the water. To allow the crocodile access to water, and to keep her from destroying the nest, traps were placed as close to the water as possible. At Turkey Point, traps were set in locations where crocodiles were known to cross roads from one body of water to another (Gaby et al. 1985). Large limestone rocks (0.3-1.0 m diam.) were strategically placed in the areas where the trails emerged from the water, directing crocodiles through the traps.

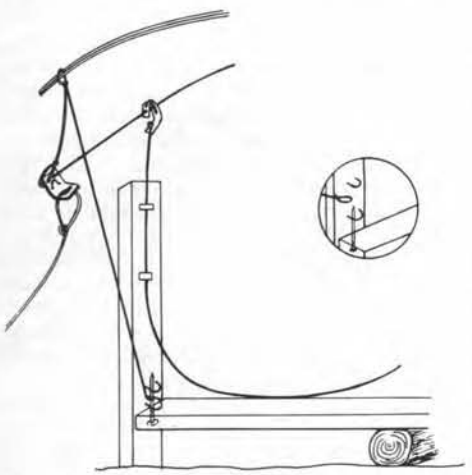

Figure 2. Closeup of trigger mechanism.

The seven female crocodiles caught in Everglades National Park in 1979 were captured in 36 trap nights during two trapping periods, for a trapping success of 19.4%. During the first trapping period five traps were set early in the incubation period on active trails at five nest sites on 30-31 May 1979. Two females were captured. One, captured 30 May, continued to visit her nest after capture and opened the nest at the end of incubation. The other animal, captured 1 June, was found dead on 10 July. Based on size (3.08 m) and tooth and scute wear, this animal was judged to be the oldest crocodile captured in South Florida, and it was not possible to determine if she died as a result of capture trauma (a blood sample was taken via caudal puncture and a radio collar was attached).

During the second trapping period, seven traps were set at five nests from 26 June - 1 July 1979. Five animals were captured. Two failed to return to the nest sites after capture. One of these nests was destroyed by raccoons, the other opened by investigators. Two animals continued to visit their nests; one nest was successfully opened by the crocodile, the other was destroyed by raccoons. No active nest was located for the fifth animal. To prevent desertion of nests, we recommend that trapping of females at particular nests be limited to early in the incubation period.

Using these methods we have been able to capture adult crocodiles that we were otherwise unable to approach. We were able to capture females known to be associated with particular nests and, by attaching radio transmitters, to obtain detailed information on their movements and habitat use. The major disadvantage of snare traps is that they must be set on an active trail. However, this technique is very effective for capturing animals known to use specific areas and has the important advantage of ease in transporting materials. Also, because it is baitless, the daily maintenance is low, and it can be used when animals may not be feeding, i.e. during the cooler months of the year.

This method has been effective in capturing *Crocodylus acutus* in Florida and *Alligator mississippiensis* in north Florida (Phil Hall, pers. com.) and with modification it should work successfully for capturing other crocodilians, particularly those that are wary and in remote areas.

ACKNOWLEDGMENTS

Support came from Florida Power and Light Co. (FPL) and the National Park Service (NPS). We thank J. Kushlan (NPS) and J.R. Wilcox (FPL) for their assistance, advice and encouragement. S. Carney and D. Phillips designed the snare trap with assistance of C.R. Stone. J. Coleman illustrated the trap. J.W. Gibbons, J.L. Knight, S.S. Novak, and R.A. Seigel offered suggestions on the manuscript. Preparation of the manuscript was supported by contract DE-AC09-76SR00-819 between the U.S. Department of Energy and The Savannah River Ecology Laboratory, University of Georgia.

BOOK REVIEWS

FACSIMILE REPRINTS IN HERPETOLOGY IN CELEBRATION OF A SILVER ANNIVERSARY

Biologia Centrali-Americana. Reptilia and Batrachia, by Albert Carl Ludwig Gotthilf Günther. 1987 (Facsimile Reprint of 1885-1902 original). (i-lxix) xx + 326 pp., 76 pls. (12 in full color). Society for the Study of Amphibians and Reptiles, Athens, Ohio, USA. Hardbound $50.

Some twenty-seven years ago one of the founders of the nascent Society for the Study of Amphibians and Reptiles (SSAR) conceived the brilliant idea of reprinting exact facsimiles of rare and significant herpetological works for its members. The society was then a tadpole at about stage 21 (Gosner 1960) in the early Ohio Herpetological Society period of development and the first facsimile reprint (E.V. Wilcox's 1891 *Notes on Ohio Batrachians*, 3 pp.) was a modest and parochial beginning. Nevertheless this unique activity (reprints of papers by Kirtland and Rafinesque-Schmaltz followed in rapid order) attracted the attention, if not the approval, of professional herpetologists to what up to then was regarded as mostly a local, amateur organization. Subsequent reprintings (from 1962 on) were to carry the bold title, Facsimile Reprints in Herpetology, and they completely changed the destiny of the fledgling society.

Following the facsimile reprinting of the herpetological portions of the 12th edition (1766) of Linne's *Systema Natura* in 1963 membership in the society nearly doubled to 291. By 1965 the formidable task of making available all of George Albert Boulenger's papers (1877-1920) on American herpetology in a uniform set was initiated to culminate some 18 parts and 900 pages later in the final section that appeared in 1977. During this period many other facsimile editions were issued, most importantly the first book-length (hardbound) reprint, Johann Jakob von Tschudi's *Classification der Batrachier* in 1967. The appearance of this work was concordant with the passage of the society through Gosner stage 46 to become the SSAR and was the visible symbol of the stability (422 members) and confidence that led to the establishment of the *Journal of Herpetology* the following year.

During the earlier period the reprints were distributed to all members without additional cost (a practice continued for the pamphlet-length series until 1979) but the Tschudi and all subsequent book-length facsimiles were available for an extra charge, albeit a substantially discounted one for members, and for sale to non-members and institutions. Reinvestment of income from these sales has allowed for the publication of a continuing series of well produced and exceptionally useful works, that otherwise could be unavailable to most members of the herpetological community because of the limited availability, rarity and cost of the originals. To date 61 separate items and more than 7500 pages have appeared as the result of the dedication of a single individual, one of the founders of what has become SSAR, the originator of the idea of the reprint series, the driving force in the development of this activity and editor of every facsimile to date, Kraig Adler.

From the point of view of SSAR the extremely successful Facsimile Reprint Series (FRS) has had several major benefits. First the uniqueness of this activity (not duplicated by any other society) gave SSAR a special identifying quality that legitimized the group as a serious scientific association. Second, it provided an unusual and valuable prerogative that aided in the recruitment of new members. Finally, income from sales of numbers in the series provided additional revenue that subsidized (and still subsidizes) the publication of the *Journal of Herpetology* and *Herpetological Review*. Under these circumstances one must attribute much of the growth and success of SSAR to this innovative publishing venture that contributes so much to the reputation and vitality of the society.

Needless to say both the SSAR and all herpetologists are greatly indebted to Kraig for his commitment to and organization of this grand project. The selection of major key works for re-publication, the overall design (especially for the book-length series), the physical reproduction and the inclusion of additional explicatory material within each work reflect his artistic, scholarly and bibliophilic talents in a most admirable combination. Adler's financial legerdemain to insure publication of the series also reveals rare skills. Few realize that he has often provided the necessary "up front" support for the printing of a particular volume, gambling that his investment would be recouped by subsequent sales. Of course his abilities as a fund raiser cannot be better illustrated than with the present reprint. After receiving an initial commitment of support from Ernie Liner, Kraig then raised sufficient matching funds to make possible the reproduction of the 12 color plates. Ernie thus deserves special recognition for his contribution to this project from all herpetologists as well.

As a user I particularly appreciate the content and format designed by the editor for the introductory materials to each major reprinted work. His philosophy has been to take advantage of the opportunity provided by the reprinting to research the topic and its author in-depth. The introductory material (Editor's Note and Introductory Essay) aims to provide all the available historical information the modern user may need. Often the Editor's Note contains important original discoveries made during preparation of the facsimile reprint, revealing, for example, the existence of many J.E. Holbrook specimens in the Paris Museum and the previously unreported expanded versions of volumes 1-2 of the first edition of his *North American Herpetology* (1836-1840) containing several new taxa, and rediscovering most of Spix's types (thought to have been lost during World War II) in Munich and Leiden.

The Introductory Essay is by a leading herpetologist intellectually connected to the subject matter of that work. These presentations invariably contain illuminating material on the life and career of the original author and the relationship of that career and the particular work at hand to the development of herpetology. Frequently they also present original ideas relating to the current state of knowledge on the subjects addressed in the reprinted volume. There is also a short biography, a bibliography of published herpetological material and a photograph or other likeness of the author of the reprinted opus. In most cases, as appropriate, a listing of mentioned taxa and their current identifications, detailed itineraries, maps of expedition routes and associated illustrations are also included. All of these materials enhance the utility of the volumes and provide intriguing insights into the particular author's life and approach to science that enhances understanding and enjoyment of the reprinted work.

All of the previous opera in the FRS and especially the books appearing in the last decade (Espada, Gloyd and Spix) are exemplars of the very best of the qualities discussed above. It is perhaps no surprise that we now have Günther's seminal work on Mexican and Central American herpetology in an edition that overshadows them all. Dear editor of the series you have outdone even yourself! What a superb production! The book itself is well-made and beautifully designed. It has an attractive art-deco lavender cover and the deep-red, leather-simulated, Tara cloth spine is embossed in gold with a Mesoamerican motif of a pair of entwined *coatls* (rattlesnakes) and the SSAR's symbol (a tree-frog) below the similarly embossed title and author information. The frontispiece is from a watercolor done of Günther in 1900 and the title-page and introductory materials are elegantly and tastefully prepared so as to blend with the original text. The plates are beautifully done, the slight reduction in size from the originals seems to have improved their sharpness without loss of intensity or color quality when compared to my copy of the original book (purchased in 1951 for $25). Overall this is a visually stunning edition! Serendipitously it also was published to coincide with the occasion of the SSAR's first annual meeting outside of the USA in Veracruz, Mexico (Adler thinks of everything!).

In terms of content this is also the best in the series thus far. Hobart M. Smith has provided a marvellously cogent, understated and succinct review of the *Biologia Centrali-Americana* (67 volumes containing 1677 plates of

which over 900 are colored), its organizers and patrons (O. Salvin and F.D. Godman) to set Günther's contribution in proper context. Both he and the FRS editor were aided in this regard by Sybil Salvin Calverley Rampen of Oakville, Ontario, Canada, who is O. Salvin's great-granddaughter. Doubtless the discovery of her existence and her ownership of many unpublished Salvin materials is another example of Adler's researching. I note a minor error in Smith's account: Carl (known as Don Carlos in Costa Rica) H. Lankester is listed as H. Lankester. He was the nephew of the eminent zoologist Ray Lankester, whose two volume (1906) history of the British Museum was so unsatisfactory to Günther, that the latter wrote a separate history of the Zoology Department (1912). Smith also has provided a listing using modern nomenclature (about 1080 species-group names) for nearly every specimen cited in Günther. The extreme value of this enumeration to the working taxonomist cannot be overestimated. For some, it alone will be worth the purchase price of this reprint. A careful review of this list shows only one erroneous identification. *Hylodes euryglossus* is based on *Eleutherodactylus fleischmanni* not *E. punctariolus.*

A.E. Günther, A.C.L.G. Günther's grandson, contributed a fascinating and personalized biography of his grandfather. The story of how the elder Günther began his career at the British Museum as a "walk-on" from the street, who was then hired for piecework identification of specimens by J.E. Gray is especially intriguing. From that position Günther, who had a medical degree and a "doctorate" in philosophy and arts, progressed to being contracted to prepare specific works, then was added to the museum's staff and finally became Keeper of Zoology. Can one imagine such a thing happening today? It's difficult enough landing a museum position under the best of circumstances without the handicap of being an immigrant with a thick accent and relatively little advanced training. One must give tremendous credit to Gray's ability to recognize potential, or perhaps it was Günther's personality and obvious talent that came through. Finally, the editor has included a bibliography of herpetological publications by Günther, who is better known as an ichthyologist than a herpetologist. On the other hand it was Günther who brought G.A. Boulenger to the British Museum to work on amphibians, reptiles and fishes and Boulenger became one of the two or three most important herpetologists of all time.

The value of having this book available again to those working on the Neotropical herpetofauna, especially in this informative and usefully supplemented edition, cannot be over-estimated. It is a "must" purchase for anyone carrying out studies on the amphibians and reptiles of Mesoamerica. All other herpetologists with an appreciation for the history of our science and the intrinsic beauty of our study organisms will find much of value here. At $50 it is a best buy!

Kraig, I hope you continue to serve as the Facsimile Reprints Editor for another quarter of a century. I don't know how you can top this production which is as near to perfect an effort as could be imagined. But don't rest too long on your laurels. I've been wondering. . . would you consider doing a facsimile reprint edition of *Beiträge zur Naturgeschichte von Brasilien, Batrachia* Vol. 1 (1825) by Prince Maximilian Wied-Neuwied?

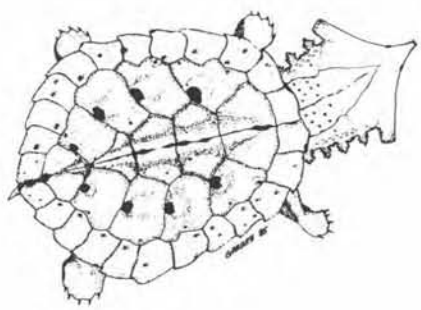
A Directory of Crocodilian Farming Operations compiled by R.A. Luxmoore, J.G. Barzdo, S.R. Broad and D.A.Jones. 1985. Jointly published by the International Union for the Conservation of Nature and Natural Resources (IUCN), Gland, Switzerland and Cambridge, U.K., and the Secretariat of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), Lausanne, Switzerland. 204 pp. Printed in Great Britain by University Press, Cambridge, England. ISBN 2-88032-809-8. £ 8 (about $12.00).

This work is a start towards providing a comprehensive listing of crocodilian farming operations which have been established throughout the world. Included are commercial operations, government and scientific research farms, and a few zoological captive breeding facilities.

To say the least, this was a most ambitious undertaking on the part of the authors. The proliferation of crocodilian farming operations in recent years has been spurred by elevated skin prices, some promising market projections, investment interest, and fashion promotions that promise to continue to bolster consumer interest in crocodilian products into the long-term future. Investors, eager to capitalize on seemingly guaranteed high returns, are often quick to back the building of such farms. They find, however, that a lack of management expertise, husbandry technology, fluctuating markets, lack of consumer interest in exorbitantly high priced products, and a nearly ten year wait before any considerable return is feasible, make crocodile farming anything but a lucrative fast turnover business. As fast as new operations appear, many disappear. Attempting to set forth such a rapidly changing listing is an accomplishment of no little merit. This work has succeeded in presenting this information.

Some of the information in the book, provided in many cases by the farming or ranching operations themselves, should be viewed with skepticism. It is interesting to note that on page 97, one farm is shown to have been established in Italy, a major tanner of caiman skins, for the broad snouted caiman *Caiman latirostris,* with breeding stock having been acquired from Colombia in 1980. However, that species is not endemic to Colombia, nor any regions in northwestern South America.

The authors point out that listings of farms do not imply credibility. The reader must decide if the operation listed is a legitimate one or not. Bogus farms may be established for the purpose of "laundering" illegal or controlled hides, and provide documentation for products made from skins of undocumented origins. A rating system for each listing, based on CITES criteria, would be of great interpretive value to the reader.



There is a lengthy introduction, written in English, French, and Spanish, which presents short overview discussions on the scope of the work and the methods employed in compiling the information, CITES controls on trade and CITES criteria for farms and ranches, captive breeding, farming and ranching finances, the impact of farming on crocodilian conservation, the effects on wild populations, habitat and species preservation, cultural preservation, and the outlook for the future. Tables include a species list with CITES status, harvest quotas for African countries, species maintained in different countries, numbers of individuals of each species, and stock and production figures.

Listings for operations are given alphabetically by country, prefaced by a short history and summary of that country's programs, protocols, and production. Each listing contains as much information about the operation as possible, including ownership, stock levels, production and financing. Wherever an operation reported activities that were not consistent with known information, every effort was made to include these questions or other comments.

Sources of information are referenced wherever possible. Two-hundred-and-twelve references are given, largely personal communications and a number of anonymous citations. The list of acknowledgments, which should include the many people who helped comment on or reviewed the text, is conspicuously brief. The methods section does not indicate what standards were used to determine scientific or common names used in the text. While the bound work cannot be easily updated, the modest purchase price of about U.S. $12.00 will bring future revisions within the range of most interests.

This work will be of greatest interest to commercial enterprises. However, it will serve as a source list for researchers and zoological institutions, and will be a valuable tool for wildlife law enforcement authorities who must scrutinize shipments of crocodilians, hides and products.

La Nomenclature Supragénérique des Amphibiens Anoures, by Alain Dubois. 1984. Mémoires du Muséum National d'Histoire Naturelle (n. s.), Serie A, Zoologie, 131:1-64, 1 Figure.

Few herpetologists approach taxonomy with as much dedication as Alain Dubois. This paper is a comprehensive treatment of the suprageneric taxonomy of anurans. Dubois has rendered a genuine nomenclatorial service by unearthing older names and forgotten literature, reflecting a brand of scholarship not likely to be appreciated by nontaxonomists. Although Dubois writes with apparent authority, alternative views exist; Savage (1986) expressed several objections, all of which were dismissed by Dubois (1987).

Dubois provides (1) six conventions to govern taxa above the family-group rank, thus extending the type-concept to those categories, (2) a list of anuran type-genera, with type-species and citations, (3) and most significantly, a family-group classification of Recent anurans. Unfortunately, the third edition of International Code (Anonymous 1985) rendered some of the nomenclature out-of-date, and Dubois later (e.g., 1985) amended his classification. Indeed, this review, first prepared in late 1985, has suffered three revisions to accommodate Dubois' modifications to the original paper.

The classification above the family level is disturbingly arbitrary. Batrachia is preferred to Lissamphibia on the grounds that it is older and used more; Dubois points out that Lissamphibia appeared only twice in titles of citations in the Zoological Record from the years 1969-1978. Batrachia is in fact the older name, but that it is more commonly used is questionable: Lissamphibia was utilized by Porter (1972); Goin, Goin, and Zug (1978); Duellman (1975); and Dowling and Duellman (1978). Also, Dubois proposes a new name (Pipoidei) for the Mesobatrachia of Laurent, (1980); the latter is abandoned because of supposed lack of use. However, given that Mesobatrachia was only proposed in 1980, this rejection is somewhat self-serving.

The most significant feature of the paper is the annotated classification of family-group taxa of frogs, previously published (Dubois 1983) without definition or diagnosis of the included taxa—interesting, considering that he (1987) chastised Savage for naming Allophrynidae and Platymantinae without definition or diagnosis. Some particulars of the family-level classification are noteworthy. Dubois regards the Discoglossidae as problematic. On the basis of biochemical data, Lanza et al. (1975) suggested that *Discoglossus* be placed in one family, and *Alytes* and *Bombina* in another. Dubois, however, feels that the degree of morphological divergence is only sufficient to warrant subfamilies: Discoglossinae and Bombinatorinae.

Dubois places some megophryine pelobatids in the subfamily Leptograchiinae. Although he (1980) previously suggested recognition of this group and the Megophryinae as tribes on the basis of tadpole morphology, he deferred action because larvae of *Leptobrachella* were unknown. Following Inger's (1983) description of those larvae, Dubois (1983) elevated the two "tribes" (previously not recognized) to subfamilies—an interesting taxonomic legerdemain.

The traditional Pelobatinae (*Pelobates* and *Scaphiopus*) are divided by Dubois into Pelobatinae and Scaphiopodinae, following Rocek (1981), who placed *Pelobates* as the sister-group to all other Salientia. If Dubois accepts Rocek's hypothesis, then the Pelobatidae of Dubois is clearly polyphyletic. Otherwise, there is no justification for subfamilies. Also, Dubois follows Laurent (1980) in elevating the Rheobatrachinae (Myobatrachidae) to a family, but later (1985) placed it and all Myobatrachidae into the Leptodactylidae without any explanation.

The treatment of the Bufonidae is particularly annoying. Following Laurent (1986), Dubois divides bufonids into the genus *Bufo*, and the Neotropical, African, and Asian clusters of non-*Bufo* genera. However, Laurent did not accord these taxonomic status; the latter three are simply geographic assemblages. Dubois, however, recognizes four subfamilies (Bufoninae, Atelopodinae, Tornierobatinae, and Adenominae, respectively). It is distressing that this arrangement is based only on geography. Worse, the content and diagnosis of the subfamilies is not given, and use of Adenominae violates the Code, because the monotypic *Adenomus badioflavus* is a synonym of *Bufo kelaartii*.

Allophryninae is recognized as a fifth subfamily of Bufonidae, following Laurent's (1980) suggestion that *Allophryne* is a bufonid. Laurent's statement was somewhat casual, and one wonders why Dubois chose to formalize this opinion. Lynch and Freeman (1966) tentatively placed *Allophryne* in the Hylidae; it is evident from their data that *Allophryne* is not related to bufonids.

Dubois' classification of firmisternal frogs recognizes Microhyloidea and Ranoidea. However, Dubois (1985) raised the Scaphiophryninae (Microhylidae) to family rank and placed the Microhyloidea in the Ranoidea, based on Wassersug's (1984) analysis, although Wassersug did not propose such an arrangement. Dubois (1986) later included Hyperoliidae as a subfamily of Arthroleptidae, and Rhacophoridae as a subfamily of Ranidae. One wonders when such juggling will stop.

Although I have severe doubts about the usefulness of the classification presented, it would have been tolerable as one more classification of anurans. Unfortunately, there were more to come (Dubois 1985, 1986, 1987). These revised classifications result largely from new opinions rather than new data. One wonders whether his first effort should be taken seriously; *La Nomenclature Supragénérique des Amphibiens Anoures* appears to be simply a point of departure for a series of somewhat capricious taxonomies. Ironically, Dubois (1986:8) wrote "Une cause particulière d'instabilité de la classification est l'existence à l'heure actuelle de plusieurs théories distinctes de la classification zoologique, dont les trois principales sont les conceptions phénétique, cladiste et synthétiste (ou évolutionniste) de celle-ci. . ."

Systematic theory has progressed beyond the point where taxonomic changes are made simply on the basis of similarity, morphological gaps, or authority. Although my perspective is admittedly phylogenetic, my criticism is not directed at the admission of paraphyletic groups, but at groups for which there is no hypothesis of relationship. Distressingly, Dubois has bestowed a patina of validity on several groups (e.g., subfamilies of Bufonidae) that are nothing more than assemblages. In this sense, Dubois' classification is a curious atavism. He does not seem to be as concerned with communicating evolutionary relationships as with providing an all-subsuming *Systema Ranarum*.

Taxonomies should reflect the extent to which phylogeny is understood; in this respect, the absence of a superfamilial classification in Duellman and Trueb (1986) is real progress. Meanwhile, the herpetological community awaits a higher taxonomy of anurans based on evolutionary relationships rather than authoritarianism.

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1988

Student member	$20.00*	Sustaining member	$50.00*
Regular member	$27.00*	Contributing member	$75.00*
Institutional	$50.00*		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

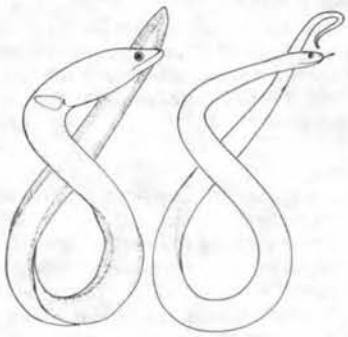
1988 JOINT ANNUAL MEETING

THE SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES, THE HERPETOLOGISTS' LEAGUE, THE AMERICAN ELASMOBRANCH SOCIETY, THE EARLY LIFE HISTORY SECTION OF THE AMERICAN FISHERIES SOCIETY, THE AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS,



Celebrating the 75th Anniversary of

COPEIA

at the

THE UNIVERSITY OF MICHIGAN ANN ARBOR, MICHIGAN

24-29 June 1988

GENERAL INFORMATION

Meeting Site

All sessions and symposia of the combined meetings of the SSAR, HL, ELHS, AES, and ASIH will be held on the campus of the University of Michigan in meeting rooms of the Rackham School of Graduate Studies, the Michigan League, and the Modern Languages Building. These buildings are adjacent to each other and two blocks from the Museum of Zoology, which will host the workshops and the live exhibit.

Dormitories for participants are 1 block east of the Museum. Hotels, diverse restaurants, bookstores, art museums, and entertainment are all within 1-3 blocks of the meeting site. Food service will also be available in the dormitories and the Michigan League. Two large University parking lots are within a block of the Museum. Airport shuttle service ($11) leaves Detroit Metro Airport for Ann Arbor every half-hour, and will stop at the Michigan League or the dormitory area when requested. Camping facilities are available 16 miles NW of Ann Arbor (see below). Weather will be warm with possible showers.

Board and Business Meetings

SSAR Board Meeting—24 June, 1000 h
HL Board Meeting— 24 June, 1600 h
ASIH Board Meeting—24 June, 1300 h
SSAR Business Meeting—26 June, 1900 h
HL Business Meeting— 27 June, 1900 h
ASIH Business Meeting— 27 June, 1900 h

Call For Papers

Titles and abstracts for papers and posters must be submitted by 1 April on a form to be mailed to each member, or which can be obtained by writing to G.R. Smith, Museum of Zoology, University of Michigan, Ann Arbor, Michigan 48109, USA. Only one paper may be read by each speaker. Additional papers may be read by co-authors or presented as posters. Late abstracts will be accepted as standby papers or (if the author consents) as posters, but not as regular presented papers. Presented papers are limited to 12 min, with three additional minutes for discussion. Speaker ready rooms will be provided for checking slides and loading Carousel trays.

Posters are encouraged especially for authors (including paper presenters) who wish to present and discuss detailed data, methods, or ideas. Large and attractive poster space (and time) will be provided. Posters will be left up one additional day.

Student Awards

Student poster presenters in the Herpetologists' League and ASIH will be eligible for Best Poster Prizes. ASIH Stoye Awards for best papers will be given in four categories: (1) general ichthyology, (2) general herpetology, (3) genetics-development-morphology, (4) ecology-ethology-environmental physiology. To be eligible a student should be a member of the awarding society and be the sole author and presenter of the paper or poster, and must indicate his or her entry category on the abstract form. (SSAR and HL students are eligible for the HL Best Poster Award.)

Registration

Registration fees are $50 regular and $25 student, with a late fee of $20 after 1 June, so please register early. The registration fee includes the Welcoming Reception on the 24th, the barbeque picnic on the 25th, refreshments at breaks and at the Auction, an abstract book, and admittance to all conference activities. There is an additional charge for the banquet on June 28th.

Registration received by 10 June will be acknowledged by mail. Non-members should write for forms and maps to U-M Extension Service, Conferences and Institutes, 200 Hill Street, Ann Arbor, Michigan 48104-3297. Members will receive forms and maps in a mailed Announcement. The fee is due in advance by check or money order, in U.S. dollars and drawn on a U.S. Bank, payable to the University of Michigan, or you may use your VISA, MasterCard, or American Express charge card for payment.

The registration desks will be open on Friday, 24 June from 0900 to 2200 h in the Lobby of the Stockwell Residence Hall. The desks will reopen at 0700 h in the lobby of the Rackham Building.

Lodging

To arrange for campus residence hall lodging, indicate your wishes when writing for

registration forms. Mosher-Jordan and Stockwell Residence Halls will house participants for the nights of 24-27 June, with breakfasts 25-28 June. Mosher-Jordan rates are: Single $118.56, Double 87.36 per person. Extra nights lodging may be reserved. Mosher-Jordan rooms are air-conditioned and have bunk sized beds. Stockwell Hall has similar rooms, but without air conditioning; rates are Single $101.92, Double $70.72 per person.

To arrange for hotel accommodations, contact the Ann Arbor Conference & Visitors Bureau, 211 East Huron, Suite 6, Ann Arbor, MI 48104. Rooms have been reserved at several hotels for meeting participants.

Recreational Facilities
An outdoor track (free) and indoor athletic building are next to the Residence Halls. Facilities include courts for racquetball, squash, volleyball, and basketball, and a swimming pool, indoor track, weight rooms, saunas and other features. Day or week passes ($3 or $9) are available.

Parking
Limited parking is available at $3.50 per day in University parking structures and lots within a block of the residence halls and the meeting buildings. Parking stickers available at the residence halls.

Camping
There is a State Park Campground (rustic) 16 miles northwest of Ann Arbor, near Silver Lake in the Pinckney Recreation Area. Directions: seven miles north of Ann Arbor on US-23 to North Territorial Road; 11 miles west on North Territorial Road to Dexter Town Hall Road; one mile North on Dexter Town Hall Road to State Park on the left.

Nearby, more civilized (RV) camping facilities with showers and swimming can be rented at Timberland Campground, 12780 North Territorial Road. Phone (313) 475-8679 or watch for signs nine miles west of US-23 on North Territorial Road.

Transportation to Ann Arbor
Ann Arbor is located on US-23 and I-94, approximately 25 miles west of Detroit Metro Airport. There is a regularly scheduled limousine ($11) between Ann Arbor and the Airport. Major car rental services are available at the airport. Ann Arbor is also served by Greyhound Bus and Amtrack.

Cultural Events
For family members, the Ann Arbor Summer Festival is a month-long potpourri of major artistic events, free movies, good food, and entertainment. The festival will be taking place during the meetings on the University of Michigan campus. Though the 1988 schedule is incomplete, the past season included such performers as Dave Brubeck, the Brecht Company, Marcel Marceau, the Harbinger Dance Company, New York's Circle Repertory Company, and many other fine performers.

SYMPOSIA AND SPECIAL SESSIONS

SSAR Regional Societies Workshop: "Exotic Places, Exotic Herps, Vol. II" (organized by Stephen Hammack)

"State of the Art—75th Anniversary of Copeia" (eight speakers, organized by Clark Hubbs)

Sessions on the ecology, evolution, natural history, and physiological ecology of amphibians and reptiles, to be arranged

Nomenclatural treatment of hybrid-derived taxa (organized by Andrew Price)

Distinguished Members from Outside the USA (organized by Clark Hubbs, Including Plenary Speakers, Distinguished Herpetologist Ilya Darevsky, and Distinguished Ichthyologist Colin Patterson)

Amphibian Reproduction and Husbandry (organized by Zoo Liaison Committee, Donal Boyer, Ch.)

Ontogeny and Systematics (organized by J. Richard Dunn)

mtDNA in Ichthyology and Herpetology (organized by Tom Dowling and Irv Kornfield)

Twelfth Annual Larval Fish Conference (organized by Neal Foster; Konrad Dabrowski, Keynote speaker)

The Biology of Chaetodontid fishes (24 speakers, organized by Phil Motta)

Catfishes of the World (organized by Carl Feraris)

Biology of Early Life-history Stages, Great Lakes Fishes (organized by Dave Jude and Nancy Auer)

Functional Development of Sensory Systems and Acquisition of Behavior in Larval Fish (organized by Howard Browman)

Special Elasmobranch Paper Sessions (organized by William Raschi)

SPECIAL ACTIVITIES

SSAR AUCTION. The SSAR Auction, Joseph T. Collins, Auctioneer, will be held on the evening of 25 June. Please bring or mail contributed items for this event to: Greg Schneider, Museum of Zoology, University of Michigan, Ann Arbor, Michigan 48109. (313) 763-4525.

SLIDE SHOWS by DAVID DENNIS—Including "Herpetology of the West"

LIVE EXHIBIT OF AMPHIBIANS AND REPTILES. To be held in the Museum of Zoology, U. of M. For arrangements, write to James Gillingham, Department of Biology, Central Michigan University, Mt. Pleasant, Michigan 48859. (517) 774-3291.

DOPEIA PAPER SESSION. Send abstracts to Joe Luczkovich, Harbor Branch Oceanographic Institute, 5600 Old Dixie Hwy, Ft. Pierce, FL 33450, before April 1, 1987. (305) 465-2400.

WEDNESDAY JUNE 29, WORKSHOPS AND FIELD TRIPS

1) Computerization of Ichthyological and Herpetological Museum Collections—Organized by Stu Poss
2) Mitochondrial DNA methods in Ichthyology and Herpetology—Organized by Tom Dowling and Wes Brown
3) Detroit Zoo (Steve Conners)
4) Belle Island Aquarium (Doug Sweet)
5) Toledo Zoo (Pete Tolson)
6) E.S. George Reserve (Justin Congdon)
7) Local Seining (R.M. Bailey, R.R. Miller, W.A. Gosline)
8) Local herpetology collecting
9) Detroit River and Western Lake St Clair fish collecting (David Jude)

Collecting Permits
For Michigan collecting permits, write to Fisheries Division, Michigan Department of Natural Resources, PO Box 30028, Lansing, Michigan 48909; Attn. Barb Walker.

Scientific Study of Museum Collections
For arrangements to study specimens deposited in the Division of Amphibians and Reptiles of the Museum of Zoology, contact Greg Schneider, Museum of Zoology, University of Michigan, Ann Arbor, Michigan 48109 (312) 763-4525.

Arrangements
For further information about registration, lodging, transportation, facilities, exhibits and arrangements, contact the University of Michigan Extension Service, Department of Conferences & Institutes, 200 Hill Street, Ann Arbor, Michigan 48104-3297, USA.

Program
For a copy of the announcement and call for papers (with abstract form) or for information about the paper sessions, symposia, abstracts, live exhibits, workshops, program, or other interests, contact the local chairman:

Gerald Smith

University of Michigan
Ann Arbor, Michigan 48109, USA ●

SSAR BUSINESS

SSAR ELECTION RESULTS

The results of the 1987 SSAR Election are as follows:

President-elect: Henri C. Seibert
Secretary: James S. Jacob
Treasurer: Douglas H. Taylor
Board - Regular: J. Eric Juterbock
Board - Regional Societies: Martin J. Rosenberg

A total of 351 members voted in this election.

The Society extends its gratitude to the Nominating Committee (Kraig Adler, Chair) and to the SSAR Elector (George R. Pisani) for their hard work, and to the outgoing President and Board Members for their service during their terms. ●

SSAR CONTRIBUTORS

SSAR wishes to recognize the following members who have contributed to the financial resources of the Society for the year 1987. These contributions make it possible for the Society to provide benefits to the membership that otherwise would be impossible. Many thanks. H.C. Seibert, Treasurer.

HR GOES HT*

Readers will notice the slightly different format and typeface of some sections in this issue, compared to the remaining sections. This reflects our first effort at desk-top publishing, a process which bypasses the typesetting tasks usually performed by the printer. Over the next few issues we will be experimenting with different styles; eventually the entire issue will be done on desk-top, resulting in savings which will allow publication of more pages in each issue of *HR*. Please bear with us (and the intra-issue style changes) as we experiment with this technique.

**High Tech* ●

SSAR COMMITTEES FOR 1987-1988

Following the Veracruz meeting, President Norman Scott appointed the following committees and coordinators for the current year to report to the Board at the Ann Arbor meeting in June 1988. Individuals with important matters pertaining to the activities of Society committees should contact the relevant committee chair. Addresses for committee chairs are included on the inside rear cover of each issue of *Herpetological Review*.

Conservation: Nat Frazer (Ch.).
Grants-in-Herpetology: Thomas H. Fritts (Ch.), Steven D. Aird, Robert N. Bader, Dale Belcher, Arthur C. Echternacht, Darrel Frost, and Michael V. Plummer.
Kennedy Student Award: J. Eric Juterbock (Ch.).
Long-range Planning: James L. Christiansen (Ch.), Sherman A. Minton, George R. Pisani, and Norman J. Scott, Jr.
Meetings: Henry R. Mushinsky (Ch.), James S. Jacob, Joseph Mitchell.
Nominating: George R. Pisani (Ch.), James L. Christiansen, John Iverson, James S. Jacob, Douglas H. Taylor, and Robert Wilkinson, Jr.
Regional Society Liaison: Stephen H. Hammack (Ch.), Fred Antonio, Mike Bumgardner, and Brint Spencer.
Resolutions: Robert A. Thomas (Ch.).
Zoo Liaison: Donal Boyer (Ch.), Dennis W. Herman, James A. Hitchiner, Brint Spencer, Ruth Zantzinger.
Common and Scientific Names Coordinator: Joseph T. Collins.
Translations Coordinator: Robert D. Aldridge.

NEWSNOTES

NEW USDI PUBLICATIONS

The United States Department of the Interior, Fish and Wildlife Service, has recently produced two publications that may be of interest to herpetologists. These are *Checklist of Vertebrates of the United States, the U.S. Territories, and Canada*, Resource Publication 166 (Richard C. Banks, Roy W. McDiarmid and Alfred L. Gardner, eds.) and *Marking and Tagging of Aquatic Animals: An Indexed Bibliography*, Resource Publication 165 (Lee Emery and Richard Wydoski, eds.). Copies may be obtained by writing to either: Publications Unit, U.S. Fish and Wildlife service, Room 148, Matomic Building, Washington, DC 20240, USA *or* National Technical Information Service, 5285 Port Royal Road, Springfield, Virginia 22161, USA.

Individuals who wish to receive product announcements of the Service's scientific publications should send their request to: Publications Coordinator, Office of Information Transfer, U.S. Fish and Wildlife Service, 1025 Pennock Place, Suite 212, Fort Collins, Colorado 80524, USA. ●

W. FRANK BLAIR AWARD

The Chihuahuan Desert Research Institute (CDRI) announces the 1988 W. Frank Blair Award competition for excellence in written data presentation. The Institute will make the $350.00 cash award to a student for the best paper, published or unpublished, pertaining to the natural sciences (including archaeology and anthropology) in the Chihuahuan Desert Region. Undergraduate and graduate students are eligible. All papers must be 7,500 words or less and must be based on original research performed by the author or authors. Entries are to be made prior to October 1, 1988. For the rules of entry write: CDRI, Blair Award Competition, Box 1334, Alpine, Texas 79831, USA. ●

"A good source of general information and marvelous stories about reptiles and amphibians."—*Herpetologica*

Their Blood Runs Cold

Adventures with Reptiles and Amphibians

Whit Gibbons

Herpetologic lore, lively anecdotal humor, and conservation ethics are combined to provide entertaining, informative reading that conveys the challenge and excitement of scientific inquiry.

Paperback, $9.95t

Tuscaloosa, AL 35487-2877

NIXON GRIFFIS FUND FOR ZOOLOGICAL RESEARCH AWARDS EIGHT GRANTS

The Nixon Griffis Fund for Zoological Research, established in 1984 by New York Zoological Society Trustee Nixon Griffis, awarded eight research grants in October 1987. Three of these grants were given in the area of herpetology. The recipients were: James C. Gillingham, Central Michigan University, "An Ethological Analysis of the Mating System of Tuatara, *Sphenodon punctatus*"; John A. Phillips and Nancy Czekala, San Diego Zoo, "Inducing Ovulation in Monitor Lizards via GnRH Therapy"; and Kent A. Vliet and Louis J. Guillette, University of Florida, "The Effect of Stocking Density on Plsama Steroid Hormone and Gonadotropin Levels in Captive-reared Alligators."

Nixon Griffis Fund for Zoological Research grants are available to members of the zoo and aquarium community. Fund recipients may be keepers, curators, veterinarians, or research and consulting biologists. Grants, not to exceed $3000, are awarded semiannually. Closing periods are 1 January and 1 July. For information about the Fund and grant application procedures, contact John Behler, Coordinator, Nixon Griffis Fund for Zoological Research, c/o New York Zoological Society, Bronx Zoo, Bronx, New York 10460, USA. ●

WORKSHOP PROPOSALS SOLICITED

The Time, Place and Program Committee (TPPC) of the American Society of Ichthyologists and Herpetologists (ASIH) has been charged with soliciting workshop proposals. Proposals for the 1989 meetings are invited at this time.

Workshops, as defined here, are distinct from symposia in that they involve hands-on experience. A workshop should provide a more thorough and complete treatment of a method or topic than one would expect from a platform presentation. Participants in an ASIH workshop should be able to leave the workshop with the ability to carry out procedures learned there or to teach what they learned to others. Workshops may involve field and laboratory exercises in ichthyology and herpetology. They could be of a systematic nature and constitute a review— with specimens available for examination—of a major taxonomic group. The TPPC is open to proposals in all areas of ichthyology and herpetology.

Each workshop should include a handout or syllabus. A typical workshop might run from 2-3 hours and have 20-24 participants, although the TPPC will consider applications for longer and larger workshops.

ASIH Board of Governors has approved cash advances of up to $300 to cover expenses (e.g. syllabus preparation, shipping workshop materials to the meeting site, etc.) in setting up each workshop approved by the TPPC. It is hoped that these funds can be recovered, in full or in part, from registration fees for each workshop.

Those interested in organizing workshops for the 1989 (*and future*) meetings should submit their proposals to: Workshop Program, ASIH-TPPC, c/o Richard Wassersug, Department of Anatomy, Dalhousie University, Halifax, Nova Scotia, B3H 4H7, CANADA.

Workshop proposals should be no longer than three typed pages and must include brief statements on the qualifications of the organizer(s), the size and length of the workshop, and the budget, if any set-up funds are requested. Proposals will be considered on a first come first serve basis. Students as well as senior members of the community are invited to submit proposals.

In order to assure a time slot in the program and funding, prospective workshop organizers should have their proposals submitted at least three weeks before the annual meeting of the year preceding the proposed workshops. All those interested in organizing workshops for 1989 should get their proposals to the Workshop Program, ASIH-TPPC, as soon as possible, preferably before 1 June 1988. ●

SOCIETIES

VHS REPRINTS TOBEY BOOK

The Virginia Herpetological Society is pleased to announce a second printing of F.A. Tobey's *Virginia's Amphibians and Reptiles*, first published in 1985. The reprinted version is identical in content to the original; a new method of binding should make the maps easier to use, however. Copies of the book may be purchased for $6.00 each, postage paid. Make checks payable to "Virginia Herpetological Society" and send to: Charles M. Neal, Department of Biology, Radford University, Radford, Virginia 24142, USA. ●

HERPETOLOGICAL SECTION OF POLISH ZOOLOGICAL SOCIETY

The Herpetological Section (Sekcja Herpetologiczna) of the Polish Zoological Society (Polskie Towarzystwo Zoologiczne) was founded twenty years ago. After a rather long inactive period, the Herpetological Section has resumed its activities. A new board elected in April, 1987, includes the following persons: M. Mlynarski (President), L. Berger (Vice-president), Z. Szyndlar (Secretary), R. Bielawski, H. Dobrowolska, J. Rafinski, and W. Zamachowski (Members). The address of the Herpetological Section is given below.

The current tasks of the Herpetological Section are: mapping of the distribution of Polish herps (as a part of the program of the Societas Europaea Herpetologica), collecting Polish herpetological literature, protection of Polish herpetofauna, and others.

The official publication of the Herpetological Section is the column "Herpetologia" in "Przeglad Zoologiczny" (Zoological Review), a quarterly of the Polish Zoological Society. Recently we have started to edit (simply as photocopies) "Biuletyn Sekcji Herpetologicznej" (Bulletin of the Herpetological Section), including current information about the activities of the Section.

The Herpetological Section is very interested in any form of contacts with other herpetological societies in other countries.

LIVE CRICKETS

. . .an excellent food source for most amphibians and reptiles.

With a dryweight analysis of 60% protein, 35% lipid and 5% carbohydrate, it is obvious why crickets are considered a valuable nutritional food source for amphibians and reptiles.

Fluker's Cricket Farm offers crickets in a variety of sizes and stages, from 1 day (1/8") to 6 weeks old (1") at a cost of $12/thousand (or a minimum order of 500 for $9.00) plus postage. Shipments are made year-round with guaranteed live delivery.

Fluker's Cricket Farm offers fine, healthy specimens. Our company takes pride in personal service, striving for individual attention and efficient shipping. We would appreciate an opportunity to serve you.

Phone (504) 343-7035.

GREATER CINCINNATI HERPETOLOGICAL SOCIETY

The Greater Cincinnati Herpetological Society, founded in 1977, provides a vehicle for information and resources exchange between its members. Through education, responsible research, and example the society zealously promotes the welfare of reptiles and amphibians.

The GCHS provides information to its members regarding herpetologically-related legislation and threatened and/or endangered species. Society members are available to community groups or educational facilities for lectures. Members are active in "white bag runs" on a year round basis, rescuing reptiles from the homes and yards of frightened or concerned citizens. These animals are released into more appropriate locations. The society sponsors periodic trips to observe the animals in the field and also behind the scenes at various zoos.

The highlight of the year is the annual GCHS sponsored "Herp Show" at the Cincinnati Museum of Natural History. Live animal displays, demonstrations and lectures draw large crowds to the museum for this exciting event.

The GCHS newsletter, published monthly and distributed to 160 members, has grown from a one page "flyer" to a professional 10-12 page bulletin which includes an illustrated cover, pertinent articles, news items, a question and answer column and classified ads. Articles and papers submitted for publication are welcome.

Membership is open to anyone with an interest in herpetology. Dues for 1988 are:

Family	$15.00
Individual	10.00
Student	8.00
Corresponding	8.00

IN MEMORIAM

JOSEPH LASZLO

"One man's *Crotalus willardi* is another man's *Lampropeltis alterna*. No man can be truly rich or free until he reproduces both in captivity!"

Joseph Laszlo
1986

It is not every herpetologist who has endured or enjoyed as varied a background as Joseph Laszlo; Superintendent of the Reptile Department at the San Antonio, Texas Zoo, he died on 14 November 1987 as a result of an aneurysm. He was born in Budapest, Hungary on 13 September 1935. His interest in natural history began to develop as a youngster and at age six, he found a water snake while collecting fish for his aquarium. This experience led to a lifetime interest in herpetology.

Times were difficult for the Laszlo family during World War II and he often told stories of great hardships. Food was rarely available and on one occasion, he was forced to eat the carcass of a dead horse. Joe developed a strong distaste for conquerers and invaders of any kind.

Joe attended Petofi Sandoa Public High School and St. Antal College in Budapest between 1945 and 1953 where he completed academic courses in literature, natural and physical sciences, mathematics, languages and art.

When he was twenty, he was drafted into the Hungarian Red Army but was forced to escape later when he turned over the keys to an ammunition depot that he was guarding to the Hungarian rebels when the Russians invaded Budapest. Several escape attempts went awry before he was able to make it to Austria. In the first attempt, he was captured by Russian soldiers at a checkpoint as he journeyed toward the Austrian border. He carried a detailed military map to assist in the escape but its discovery would have led to instant death; he swallowed it as he sat between two machine gun-laden Russian soldiers. The Russians turned Laszlo over to the Hungarian Army after a three day detention. The second escape attempt was no more successful. A sympathetic Hungarian soldier allowed him to hide under a pile of hay but Joe had hay fever. The journey was arduous as he tried to control his sneezing. Unfortunately, as he slipped off the hay truck to continue his escape, he discovered in horror that the driver had disembarked at the same Russian control post where he had been detained earlier. Finally, after a few more false starts, he arrived at the Austrian border aboard a train where he walked across the Andau Bridge to freedom. He stayed in a Red Cross camp in Vienna until he was able to arrange passage to the United States.

Immediately upon arrival, Joe began a pilgrimage through the US to locate herpetologists by searching for their addresses in the herpetological literature. Since he was not conversant in English, he communicated with gestures, drawings and by using scientific names, and was able to get his points across to his colleagues. He was awarded a scholarship, through the efforts of Wilfred Neill, to the University of Florida in 1957 but unfortunately lost it due to the language barrier.

In 1963, he became a US citizen and worked for the Humane Society of Greater Miami, Florida. His first job at a zoo was in 1963-1964 at the Crandon Park Zoo in Miami, Florida.

I initially met Joe in the Fall of 1965 while employed as a reptile keeper at the Atlanta Zoo. His boundless enthusiasm and absolute dedication to herpetology were awe-inspiring. Joe was a raconteur par excellence and often he would regale any assembled throng of herpetologists with anecdotes of his early days in Europe, his theories on captive reptile management and, finally describe his Weltanschauung in elaborate detail. Many pleasant hours were spent listening to him as he

Joseph Laszlo holds two newly hatched water monitors at the San Antonio Zoo during February 1981. Photograph by John Tashjian.

punctuated his stories with wonderful facial expressions and charming imagery.

Joe was hired as a keeper at the Columbus Zoo by the late Louis Pistoia but alas, the association was tumultuous. Pistoia directed him to clean the king cobra enclosure but no shift box was in evidence. Understandably Joe was reluctant to enter the cobra's domain and he expressed his reservations vociferously. To demonstrate, Lou proceeded to enter the cage, stimulated the snake to rear its magnificent body and then tied a handkerchief around its eyes so that it could not see. In response to this, Joe quickly sought employment elsewhere.

Joe and I arrived in Texas in tandem in 1966, Joe to the Ft. Worth Zoo as assistant supervisor at the Herpetarium and I to the Dallas Zoo. Joe's ideas on proper captive reptile care were beginning to solidify and he investigated thermoregulation, medical treatment, feeding techniques and so on in meticulous detail. In fact, as a measure of his commitment, his house had virtually no furniture but rather was filled with an impressive array of terraria, herpetological literature and diagrams of heating elements, enclosures, cooling devices, myriad paraphernalia and lists of medications for reptiles.

In an effort to expand his horizons, Joe secured a position at the Houston Zoo in 1966. He admired John Werler, herpetologist and Director of the Zoo, who had a Mexican natricine snake *(Nerodia rhombifera werleri)* named in his honor. During one of my visits to the Zoo, Joe, in a state of abject despair, lamented how he had accidentally fed some of John's namesakes to the king cobra. . .in fact, the snakes which were fed were some donated *Nerodia r. rhombifera* from Texas, and his coworkers, with John's complicity, had foisted an elaborate practical joke upon Joe by insisting that the snakes were *werleri*. Days passed before the practical joke was exposed as Joe ruminated about his future in the zoo profession.

In response to Joe's interest in cooling and hibernating reptiles to elicit reproduction, the staff at the Houston Zoo began experimenting with techniques and soon the service area was filled with reptile enclosures, festooned with dials and gadgets, of every size and description. One evening in Houston, as a group of us were sitting around talking about reptilian husbandry as related to cooling our charges, an atrocious foreign movie about an attack of dinosaurs on a heavily populated Japanese city flashed on the television. We began speculating how these creatures, if they now existed, should be maintained in zoological gardens. Joe, after deliberate thought, rolled his eyes skyward and said "You've got to keep them cool, mon" with absolute certitude. With that statement, he deftly solved the controversy surrounding dinosaur thermoregulation.

Joe's final position was Superintendent of Reptiles at the San Antonio Zoo in 1970 where his creative energy flourished. He embarked on a series of projects related to lighting, heating, cooling, and exhibitry of reptiles and amphibians. A visit to view his charges was always exciting. Joe, with stupefying energy, opened virtually every enclosure, gave a detailed history of the inhabitant, recaptured those few creatures which had exited their cages as he was speaking, and presented detailed taxonomic information and literature citations for each.

Joe's particular passion was directed toward reproduction in the Old World vipers *(Vipera);* he often said that he wanted to reproduce vipers in such numbers that. . ."The snakes would cover the world like Sherwin Williams paint, mon."

It is likely that there have been herpetologists who have had more impressive credentials or higher visibility in the herpetological community. But it is unlikely that any will be as sorely missed as Joe. Ever the devoted father, he was generous, kind, helpful, creative and maintained a remarkable enthusiasm for herpetology, mostly self-taught, for over forty years. We will all miss his unique and colorful view of life. No doubt, Joe has already convinced St. Peter to remodel the Heavenly Gates into an entrance for his new reptile building.

MEETINGS

ALL FLORIDA HERP CONFERENCE

The eleventh annual All Florida Herpetological Conference will be held April 23 at the University of Florida. The conference is cosponsored by the Florida State Museum and the Gainesville Herpetological Society. Program themes will be "Conservation of Herps and Habitats," "Outdoor Enclosures for Exhibiting and Breeding Amphibians and Reptiles," and "Public Education and Herpetology." Workshops in "Still Photography of Amphibians and Reptiles" and "An Introduction to Herpetology for Children" will also be offered. Registration and program information is available from Rhoda Bryant, Florida State Museum, Museum Road, Gainesville, Florida 32611, USA. (904) 392-1721. ●

SIXTH SYMPOSIUM ON AFRICAN AMPHIBIANS (organized by the African Amphibian Working Group)

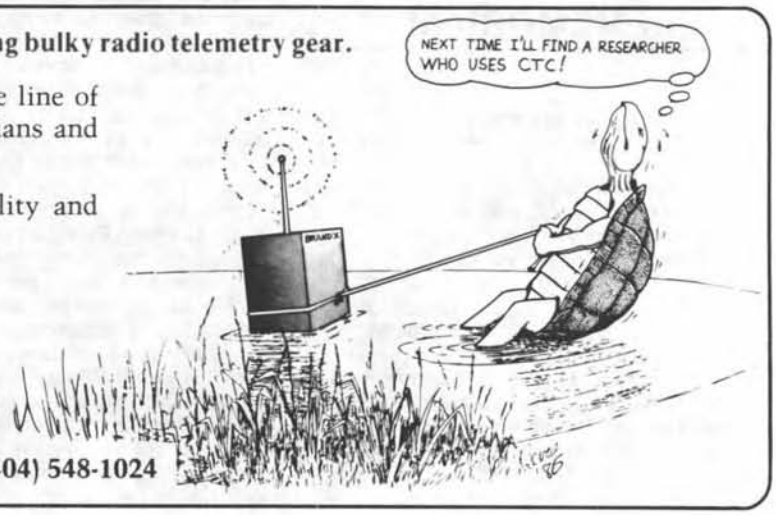
The Sixth Symposium was held 13-17 April 1987 under the sponsorship of the University of Miami, at the Archbold Biological Station near Lake Placid, Florida. A summary of the program appears below.

Tuesday, 14 April
Morning Session
Introduction to the Archbold Biological Station - James L. Wolfe, Executive-Director, Archbold Biological Station
Review of Project on Locally Endemic African Amphibians - David Stubbs, Ecological Consultant to IUCN Conservation Monitoring Centre, Cambridge, Great Britain
Tour of facilities and 4,300 acre Biological Station - Fred S. Lohrer, Scientific Assistant, Archbold Biological Station.

Afternoon Session - Alan Channing, chairperson
Evolutionary Morphology and Relationships of the Pipid Genera *Hymenochirus* and *Pseudhymenochirus* - David Cannatella, University of California, Berkeley, USA
Discussion of Pipid Relationships and the Resurfacing of *Silurana* (the catfish frog) - Linda Trueb, University of Kansas, USA
The Genus *Hyperolius* or the *Hyperolius viridiflavus* Group Revisited - Alan Channing, University of the Western Cape, Vellville, R. South Africa
Comparative Lingual Morphology and the Relationships of African Ranids - Jean-Luc Perret, Museum historie naturelle, Geneve, Suisse
A Review of Ranoid Relationships - Raymond F. Laurent, Fundacion Miguel Lillo, Universidad de Tucuman, Argentina

Evening
Field trip to collect local amphibians - David M. Hillis, guide

Wednesday, 15 April
Morning Session - Rose Bloomers-Schlosser, Chairperson
Some Ecological Interactions of new *Xenopus* Species Endemic in Montane Regions - Richard C. Tinsley, Queens Mary College, University of London, Great Britain
Aftican Bufonids and Their Habitats - Mills Tandy, Austin Community College, Texas, USA
Reproductive Modes in Malagasy Anura - Rose Bloomer-Schlosser, Institute For Taxonomic Zoology, University of Amsterdam, Netherlands
Status of the African Amphibian Bibliography - D.E. van Dijk, University of Natal, South Africa (presented by Alan Channing)
Discussion: Ecomorphological Guilds of Anuran Tadpoles - Ronald Altig*, Mississippi State University, USA and Gail F. Johnston, Southern Illinois University, USA



Afternoon Session - Rose Bloomers-Schlosser, chairperson
Fertility conditions in F_2 hybrids between *Xenopus l. laevis* and *X. gilli* - Hans Rudolf Kobel, University of Geneve, Suisse
The Inheritance of Color Pattern and Sex in *Hyperolius v. viridiflavus* - Christina M. Richards, Wayne State University, Michigan, USA
The Structure of the Carpus in Some Primitive Ranoid Frogs - Raymond F. Laurent* and Marisa Fabrezi, Fundacion Miguel Lillo, Tucuman, Argentina

No species of study should be burdened with carrying bulky radio telemetry gear.

Custom Telemetry & Consulting offers a complete line of external and implantable transmitters for amphibians and reptiles with a wide range of options.

Custom design, high quality components, reliability and reasonable prices...that's *CTC.*

Please inquire for more detailed information.

Custom Telemetry & Consulting, Inc.

185 Longview Drive □ Athens, Georgia 30605 □ (404) 548-1024

Rainforest Conservation in Costa Rica: a model - Mills Tandy, Austin Community College, Texas, USA

Evening
Field trip to collect local amphibians - David M. Hillis, guide.
Post-field trip evening Social: Darrel Frost, guide

Thursday, 16 April
Morning Session - Richard C. Tinsley, chairperson
Biosystematics of Selected Genera of African Amphibians - James P. Bogart*, University of Guelph, Canada and Mills Tandy, Austin Community College, Texas, USA
Crosses Among Various Groups of *Hyperolius* - Christina M. Richards, Wayne State University, Michigan, USA
Establishment of African Parasites in the USA with Feral *Xenopus* populations - Richard C. Tinsley, Queen Mary College, University of London, Great Britain
Polymorphism versus Polyploidy, the Example of *Xenopus l. laevis* - J. Wolff and Hans Rudolph Kobel*, University of Geneva, Suisse
Discussion: Endemic African Amphibians and Conservation Areas - David Stubbs, IUCN Conservation Monitoring Centre, Cambridge, Great Britain

Friday, 17 April
Field trip to Everglades - David M. Hillis

* = Speaker

The African Amphibian Working Group will hold an open meeting at the time of the first World Congress of Herpetology (WCH) at Canterbury (U.K.), 11-19 September 1989. The purpose of the meeting will be to update the working group membership and select a site and date (in 1991 or 1992) for the 7th Symposium on African Amphibians. All individuals interested in African amphibians are invited to attend. Professor Alan Channing, Biochemistry Department, University of the Western Cape, Private Bag X17, Belleville, 7530, Republic of South Africa, will coordinate the WCH session and may be contacted regarding that meeting and/or the 7th Symposium.

SEXUAL BEHAVIOR OF THE CASPIAN TERRAPIN, *Mauremys caspica rivulata*

The Caspian terrapin *Mauremys caspica* occurs in the Near East from the Caspian Sea and the Persian Gulf in the east to the Balkan in the west. The subspecies *M.c. rivulata* is known from the Mediterranean region and *M.c. caspica* is known in the eastern parts of the species range (Busack and Ernst 1980). In Israel, where *M.c. rivulata* reaches its southern limit of distribution, it occurs in a wide range of fresh and brackish water habitats, of standing or slow flowing water, including highly polluted waters (Gasith and Sidis 1983, 1984). The period of sexual activity (courtship and copulation) of *M.c. rivulata* in Israel extends from September until May, peaking in mid winter. Sexual activity may take place at temperatures as low as 8°C (Gasith and Sidis 1985). Males of *M.c. rivulata* are slightly smaller (80-220 mm CL) than the females (140-240 mm CL) and are usually more intensely colored.

Scant information is available on the sexual behavior of *M. caspica* or its closely related species *M. leprosa* (formerly *M. c. leprosa*, Busack and Ernst 1980). According to Lortet (1887) *M. leprosa* mates on land or in water. When in water, it is usually on the surface though sometimes a mated pair may be seen descending to the bottom where they remain immobile for several hours. Gadow (1920) reported that in mating, the male of *M. leprosa* tries to fasten onto its mate by biting into the collar-like fold of the neck, into which her head is withdrawn. This repeated irritation may inflict serious injury to the female. Glass and Meusel (1964) reported that *M. caspica* mates in water and that copulation is preceded by courtship. In reviewing the evolution of stereotyped behavior in reptiles, Carpenter and Ferguson (1977) summarize the behavioral patterns and act systems observed in turtles relating primarily to intraspecific aggression, courtship and mating. For *M. caspica* these are (based on Gadow 1920; Loveridge and Williams 1957; Eglis 1962): sinking to the bottom, withdrawing head into shell, pulsation of gular region, biting. Berry and Shine (1980) classified *M. caspica* among the truly aquatic species in which males are usually smaller than females, and male combat and forcible insemination are rare. Instead, males utilize elaborate precoital display and female choice is highly important.

During 1979-1982, we observed the sexual behavior of this species in its habitat in Israel and in captivity (53 and 58 observations respectively). The study sites in Israel are described elsewhere (Sidis and Gasith 1985; Gasith and Sidis 1985). The following is a composite description of the courtship display and mounting behavior of *M. c. rivulata*.

Courtship and mounting usually take place in shallow water (< 30 cm depth). On two occasions courtship was initiated in water but continued on land near the water's edge. In courtship, a male or a group of up to six males pursue an adult female. In the latter case the largest male usually leads the chase. In most cases the males are either equal to or smaller than the courted female. The smallest courting male recorded in this study was about 80 mm in carapace length (CL) (1-2 years) and the smallest courted female was about 150 mm in CL (4-6 years, age determination based on growth rings). The male crawls on the bottom or swims behind the female, his neck fully extended and head behind the female's hindquarters, his snout almost touching her vent. During this interaction the male intermittently pulsates his gular region (several pulses per second) and may occasionally

bite her hindleg or carapacial margin. Then the male circles or partially circles the female, occasionally biting her legs and the edge of her carapace. The longest duration of this portion of the courtship display recorded in this study was about 15 min and the maximum distance covered was about 30 m.

When the female stops moving the male moves in front of her, faces her from a distance of about 30 cm and then approaches her while swaying his head and intermittently pulsating the gular region. Eventually he reaches with his head to one or the other side of the female's head and retreats backward. This behavior is usually repeated several times, lasting overall about two min. Following this face to face interaction the male moves behind the female and mounts.

During the period of peak sexual activity (December-January) mounting sometimes occurs without courtship display. This was observed when males and females were temporarily placed in a small container in which the turtles' movements were limited. This observation is consistent with the view that courtship serves to immobilize the female and facilitates mounting attempts by the male (Eglis 1962; Jackson and Davis 1972).

Two extreme postures could be distinguished in the mounting phase. (a) Horizontal (riding) position in which the male is astride the female's carapace, gripping the edges with all four legs. In this position the male is able to maintain his hold if the female resumes swimming. The male's neck is fully extended and the head is lowered over the female's head, occasionally biting her neck. The male sways his head with intermittent pulsation of his gular region. Unlike Gadow's (1920) report of severe biting by male *M. leprosa*, we recorded only gentle bites in *M. c. rivulata*. The female usually responds by partially or completely withdrawing her head into the shell. At any time during this phase the male may lower his tail towards the female's vent. (b) An oblique mounting position which differs from the horizontal posture in that the male holds onto the female's carapace with forelegs only, supporting his body in an oblique position to that of the female's body. Varying degrees of horizontal to oblique postures were recorded and it is possible that the above positions reflect different phases of the mounting behavior. However, we have no evidence for position changing by the mounting male, as for example the backward sliding reported in *Emydoidea blandingi* (Baker and Gillingham 1983). Mahmoud (1967) observed variations in the mounting postures within species of kinosternid turtles which he could relate to size difference between the mates. We have found no evidence for such correlation in *M. c. rivulata*.

In nature we followed mounted pairs for up to 30 min. On three different occasions, in captivity, we observed pairs that remained mounted from early morning until after dark and these same pairs were still mounted also on the following morning. Homosexual interaction was observed once in captivity: A male mounted another male, performing the normal head swaying and neck biting. In nature, *M. c. rivulata* proved to be extremely alert to approaching humans, quickly submerging into the water and fleeing. However, courting and especially mounted individuals were quite oblivious to such interruptions and were easily taken by hand.

Various elements of sexual behavior of turtles (reviewed in Carpenter and Ferguson 1977) are found also in *M. c. rivulata*. These include trailing and pursuit of female, moving around the female, face to face interaction, biting, head swaying, pulsation of gular region, holding onto female with hind and forelegs or forelegs only. Unlike some other turtles *(Chrysemys, Pseudemys, Graptemys)* the face to face interaction of *M. c. rivulata* involves no titillation but is composed of a series of approaches and retreats of the male accompanied with head swaying and pulsation of the gular region.

ACKNOWLEDGMENTS

We wish to thank H. Mendelssohn, W.L. Werner, A.S. Perry and J. Hoofien for their valuable remarks on the early version of this manuscript.

YOUNG OF THE YEAR RED-SIDED GARTER SNAKES *(Thamnophis sirtalis parietalis)* AT COMMUNAL DENS IN MANITOBA'S INTERLAKE REGION

Fall aggregations of red-sided garter snakes *(Thamnophis sirtalis parietalis)* at hibernacula in Manitoba's Interlake region are usually composed entirely of adults (Aleksiuk and Gregory 1974; Gregory 1974; Gregory and Stewart 1975). There are no records of young of the year occurring at den sites in fall. However, while conducting a mark and recapture program near Broad Valley, Manitoba (approximately 100 km north of Winnipeg), two young of the year snakes were captured on 21 September 1985.

Previous literature has suggested that it would be advantageous for young snakes to remain afield in fall rather than undertake long migrations to the dens. In this way, they may continue to feed until immediately before hibernation and thus attain an earlier sexual maturity (Gregory and Stewart 1975). During winter, young snakes would be obliged to find alternative denning areas, such as animal burrows or post holes. However, pregnant females may not give birth in summer feeding habitat (usually marshland some distance from the den site) but may bear their young during migration back to dens. If this occurs, young might travel to dens with adults to assure themselves a suitable hibernaculum, as they have lost the opportunity to remain in the summer feeding habitat. Such a scenario may occur if embryo development is delayed by a cool summer, such as that of 1985 in the Interlake region of Manitoba. The relatively large number of gravid females found at dens in fall 1985 further supports this interpretation, as few gravid females are normally encountered during fall migration (Aleksiuk and Stewart 1971). It is hypothesized, therefore, that young of the year normally spend their first winter afield on summer range. They may be found at communal dens in fall if the preceding summer had been cool enough to prolong the gestation period of part of the female component of the population.

REDISCOVERY OF THE HOLOTYPE OF *Ophisaurus ventralis sulcatus* (COPE)

Opheosaurus [sic] *ventralis attenuatus* var. *sulcatus* (Cope 1880. Bull. U.S. Natl. Mus. (17):1-51) [*Ophisaurus v. sulcatus* (Cope 1900. Ann. Rep. U.S. Natl. Mus. for 1898: 153-1249)] was described on the basis of one specimen from Dallas, Texas. *O. v. sulcatus* has been placed correctly in the synonomy of *O. a. attenuatus* (McConkey 1954. Am. Midl. Nat. 51: 133-171), the only glass lizard known to occur in Texas, but the holotype apparently has not been examined since the original description (Holman 1971. Cat. Amer. Amphib. Rept.: 111.1-111.3).

The type, collected by J. Boll, and originally in Cope's personal collection, has been found in the Philadelphia Academy of Natural Sciences (Malnate 1971. Proc. Acad. Nat. Sci. Philadelphia 123: 345-375) and examined by me. It is a juvenile (ANSP 12755), about 87 mm SVL, with a single frontonasal, 105 scales along the lateral fold, and color patterns typical of those in young *O. attenuatus*. The eighth supralabial on the left side is separated from the orbit by two small scales, although one of several early drawings (Cope 1900, fig. 89) shows this labial contacting the orbit. The remaining suborbital supralabials are separated by prominent lorilabials, and other scale configurations in the specimen agree with those depicted in the Cope drawings. All characters in ANSP 12755 are well within the range of variation reported by McConkey (1954) in *O. a. attenuatus*.

I thank E. V. Malnate for allowing me to borrow this specimen and for confirming the presence of certain characters after it had been returned.

A PLEA FOR STANDARDIZATION OF BODY SIZE MEASUREMENTS IN STUDIES OF SNAKE ECOLOGY

Body size[1] has been found to exert an important influence on the ecological characteristics of snakes, especially in the areas of life-history evolution (Dunham and Miles 1985) and foraging ecology (Mushinsky et al. 1982). Data that can be used to correlate ecological traits with body size are crucial to a complete understanding of the evolutionary ecology of ophidians. However, while conducting several recent reviews of the literature on snake reproductive biology, we noted a lack of standardization among herpetologists concerning which body size measurements are recorded and reported, and suggest that this lack of standardization hampers efforts to advance our knowledge of snake biology. The purpose of the paper is to demonstrate the lack of consistency in body size measurements, and to establish some basic criteria for reporting measurements. Although our comments are addressed primarily to researchers working with snakes, it is likely that investigators working with other taxa face similar problems.

The three most commonly-reported measures of body size are snout-vent length (SVL, the distance from the tip of the snout to the posterior edge of the vent), total length (TL, the distance from the tip of the snout to the posterior tip of the tail), and body mass (BM, total mass in g). Convincing biological arguments can be made for recording all three measures. The two length components show significant correlations with reproductive traits such as clutch size, clutch frequency, and offspring size (Shine 1977; Ford and Killebrew 1983; Seigel and Ford 1987) and SVL exerts a strong influence on other life-history characteristics (Dunham and Miles 1985). Body mass is also important in life-history correlations (Hedges 1985), in calculating relative clutch mass (Seigel and Fitch 1984), and in calculating metabolic rates (Bennett 1982). Of the two measures of length, we suggest that SVL is more important, primarily because it obviates the problems of tail breakage (Fitch 1987). In addition, because the length of the tail is often sexually dimorphic (Fitch 1981), it should be reported either as a discrete entity or by subtraction of SVL from TL, permitting calculation of relative tail length (tail length/SVL). Fitch (1987) and Vitt (1987) provide further details on these and other morphological measurements that are relevant to snake ecology.

Although it seems apparent that complete reporting of body size measurements (SVL,TL, and BM) is important to ecological studies on snakes, complete records in the literature are the exception rather than the rule. While examining the literature on relative clutch mass (RCM) in snakes, we found that less than 50% of the studies reviewed reported data on the mass of both the female and the offspring (Seigel and Fitch 1984). Later reviews of the relationship between RCM and body size (Seigel et al. 1986) reinforced the view that complete data on body size were reported rarely. In order to determine quantitatively the extent of this problem, we examined back issues of *Herpetological Review* from 1984-1986 for studies on snake foraging and reproductive ecology, then scored each study as to the measurements reported (e.g., SVL alone, TL alone, complete data, etc.). Where data for parents and offspring were reported differently, we scored the paper as two studies. Of the 36 studies examined, complete data (SVL, TL, and BM) were reported in only eight (22.2%). Data on SVL alone were reported in 19.4% of the studies, and TL alone in 13.9%. Information on mass (alone or in combination with either SVL, TL, or both) was reported in less than half of the studies (47.2%). In 13.9% of the studies, the measure length was either not specified as to SVL or TL, or no body size measure was reported. (A complete breakdown of all categories is available from the senior author.) Although we recognize that we examined only a limited number of papers from one journal, this matches our subjective impressions from a wider literature review covering 30 years and more than a dozen journals.

We suggest that this lack of uniformity in body size measurements seriously hinders the advancement of our knowledge of snake ecology. Many of the life-history and ecological reviews cited previously were dependent primarily on empirical data drawn from the literature. It is extremely frustrating to search for a reference on a poorly-known species, finally find it, then be unable to utilize otherwise high-quality data because the author failed to include the necessary measurements. Far too little is known about the ecology of snakes to have to disregard 50% or more of the literature.

We strongly encourage investigators to include the three basic measures of size, or at least, SVL and BM. Recording both SVL and TL takes only a few more seconds per specimen than recording just one measure, but may significantly enhance the usefulness of the data.

Although recording BM may have been difficult in the past, the advent of inexpensive, portable, and accurate spring scales means that BM can be recorded in the field in just a few moments.

Editors and reviewers too must accept some responsibility for this lack of uniformity. Although reporting all three measures takes only a little more space than reporting just one, it is likely that editors and reviewers have not sufficiently encouraged authors to include these measures in their papers. In some cases, editors have apparently discouraged the practice. One researcher we spoke with said that he would have included BM more frequently in his papers, but had been told by editors that "no one cares about weight." We suggest that editors and reviewers have an obligation to encourage authors to report complete data on body size, even to the point of rejecting papers that fail to include the necessary information.

It is not our intention to criticize the research of any individual. Clearly, studies are conducted for a variety of reasons, and the measurements suggested here may not be of immediate interest to the investigator. Nonetheless, reporting standardized body measurements may greatly increase the potential value of the research. In a similar manner, it is not our goal to denigrate the quality of the papers published by *Herpetological Review*. Indeed, we deliberately selected *Herpetological Review*, both for our database and as a publication outlet, because it publishes papers from a wider variety of sources then is true for other herpetological journals, with contributors ranging from professional herpetologists to amateur naturalists. It is to this diverse audience that we address our "take-home message" to record and report SVL, TL, and BM of snakes whenever possible. Although the data may not seem important at the time, some future herpetologist may be grateful for your extra effort.

[1]S. Moody (per. comm.) has correctly pointed out that the term "body size" formally refers only to that part of the body exclusive of the head and tail, so our use of "body size" should be considered in the broader sense of the term.

ACKNOWLEDGMENTS

We thank H.S. Fitch, J.W. Gibbons, J.L. Knight, S. Moody, and three anonymous reviewers for comments and discussions on this paper. This research was partially supported by DOE Contract DE-AC09-76SR00-819 between the U.S. Department of Energy and the Institute of Ecology, University of Georgia.

A NOTE ON THE DISTRIBUTION OF *Eleutherodactylus eileenae*

Eleutherodactylus eileenae Dunn is one of six species comprising the *auriculatus* group of Cuba. Schwartz and Thomas (1975) reported the species' distribution as from Pinar del Río to Camaguey Province, but noted a questionable record isolated from Oriente Province, eastern Cuba.

My purpose is to clarify the identity of this specimen, and the distribution of *E. eileenae*. The specimen is an immature female (SVL 22.2 mm) collected by Philip Darlington in Cueva de la Ma, Pico Turquino, and deposited in the University of Michigan (UMMZ 80910). Although a member of the *auriculatus* group, it is not *E. eileenae*, from which it can be distinguished by: dorsum uniform, with flanks somewhat darker in the anterior third (a double scapular chevron characterizes *eileenae*); a faded papilionaceous interorbital figure (not present in *eileenae*); supratympanic stripe faintly expressed, (*eileenae* shows a well-defined stripe); supralabials lacking the alternate pattern of dark and light spots of *eileenae*. *Eleutherodactylus eileenae* has a moderately dark throat, whereas in this specimen the throat is lighter. The head appears to be wider than in individuals of *eileenae* of the same size.

These characteristics, as well as other body measurements, suggest that the specimen is *Eleutherodactylus varians ionthus* Schwartz, a form distributed in Oriente Province. Hence the distribution of *E. eileenae* is the rest of the island.

I thank Dr. Richard G. Zweifel, American Museum of Natural History, who kindly borrowed the specimen for me, and provided the material for comparison.

Herpetological Husbandry

This section of **Herpetological Review** deals specifically with the husbandry of captive reptiles and amphibians. Articles concerning any aspect of successful exhibit design, techniques for maintenance and breeding, egg incubation, and rearing of the young are acceptable based on the success of the husbandry program, the quality of written work, and the overall value of the presented material to the herpetological community. Reproductive articles should stress the actual methods and specimen manipulation involved but may also include observations of behavior, growth, and statistical data. Of particular interest are reports describing consistently successful, long term programs which deal with large numbers of a single species or genus.

Longer husbandry manuscripts should be divided into appropriate sections including Literature Cited. Black and white photos and line drawings are acceptable. All manuscripts will be reviewed by the Section Editor, and frequently by another individual within the particular area of expertise. Reports which do not deal with herpetological husbandry *per se* (for example, the description of eggs and young from a wild-caught gravid female) will be forwarded to the Editor for consideration as a Feature Article. In order to reduce publication time, husbandry articles should be sent directly to the Section Editor, Bern W. Tryon, Knoxville Zoological Park, Box 6040, Knoxville, Tennessee 37914, U.S.A.

REPRODUCTION AND GROWTH OF THE CHELID TURTLE *PHRYNOPS (MESOCLEMMYS) GIBBUS* AT THE COLUMBUS ZOO

Aspects of reproduction in *Phrynops gibbus* have been reported by several authors and summarized by Pritchad and Trebbau (1984). Available information on egg laying consists of five clutches reported by Niceforo (1952), Medem (1973) and Dixon and Soini (1977). Information regarding growth, beyond the nine month growth data presented by Medem (1973), and maturation is not presently available.

Specimens housed at the Columbus Zoo have produced 14 clutches of eggs from 1978 through 1985. In addition to clutches laid by wild collected but long term captive animals, these include clutches laid by specimens hatched in the collection and reared to maturity. One additional clutch, laid by a recently collected female, is also reported.

The original breeding pair consisted of a 15.7 cm carapace length (CL) male, donated 28 June 1968, and a 21.8 cm CL female obtained on breeding loan from the Detroit, Michigan, Zoo 30 June 1977. This pair produced seven clutches of eggs from 28 February 1978 through 27 August 1982. The last of these, non-viable during incubation, was produced following reintroduction of the male after a 19 month isolation for treatment of trauma and prolapse of the penis. A large amount of tissue was sloughed from the penis due to necrosis. No eggs were produced by the female during the isolation of the male, but the 27 August 1982 clutch was produced ca. two months after reintroduction of the male. Progeny from 1978 and 1980 began producing eggs in 1985, and have produced five clutches to date. An additional female, 17.8 cm CL, was donated 25 January 1984 after being held by a private collector for ca. 18 months. This animal produced two clutches in 1985.

HUSBANDRY METHODS

Adults have been housed in an irregularly shaped display tank, ca. 140 cm square, with a water depth of 50 cm. A basking site and sand pit are provided ca. 12 cm above water level. Cage lighting, provided by two 30 watt fluorescent tubes (G.E. Chroma 50 series), is controlled by a timer set to approximate the photoperiodic variation of 15° N. latitude. Water temperature is maintained between 20 and 24° C, with air temperature varying from 24 to 32° C during the year. A variety of other forms of turtles have been housed with the *P. gibbus* over the years. Diets for units such as these are not formulated for specific forms, but are designed for the mixed species groups occupying the tank. Thus, until 1979, the *P. gibbus* were offered one feeding per week of cut horsemeat or cut freshwater smelt, and two feedings per week of serially fed produce. In 1979, a fourth feeding per week was added to these, consisting of pelleted commercial diet (Purina Trout Chow). Earthworms, chicken livers and hearts, mealworms, and since 1984 crayfish and mystery snails have been offered as occasional supplementary feedings. Diet of hatchlings and juveniles has approximated this, with the substitution of pelleted trout chow for one weekly produce feeding, and four to five feedings per week. Observations of all age classes support the statement of Mittermeir et al. (1978) that diet is primarily carnivorous, but that plant matter is occasionally taken. While greens and fibrous vegetables (e.g. kale, lettuce, spinach, celery, carrot and sweet potato) are seldom ingested, fruits (e.g. apple, grape and particularly banana) are eaten regularly.

Most eggs have been buried in the sand pit to depths of 2 to 12 cm. In periods when more than one female was housed in the tank, identification of the egg laying female has been made by observation of oviposition, or vation of pre-nesting digging coupled with palpation of eggs through the inguinal area of the female. Eggs are removed soon after oviposition, and incubated in a 1:1 mixture (by weight) in sealed gallon jars or equivalent containers. Jars are vented every 4 to 6 weeks, and some have been repotted with a fresh mixture of vermiculite at 100 day intervals. Some clutches were heavily misted with tap water when hatching seemed imminent due to the appearance of scratches on the inner aspect of the outer shell. Incubation temperatures have varied from 26 to 31° C.

RESULTS AND DISCUSSION

Dates of egg laying, clutch sizes, egg sizes and weights, and incubation periods for the 14 clutches produced in this collection are summarized in Table I.

Nesting dates for recently collected specimens have been reported for only two specimens. Medem (1973) reported the laying of a clutch on 23 November by a specimen from Rio Vaupes, Colombia, and Dixon and Soini (1977) reported the laying of a clutch on 3 August by a specimen from Iquitos, Peru. An additional specimen, recently imported and referable to specimens noted by Pritchard and Trebbau (1984) to have been collected in southern Surinam for export in the live animal trade, was acquired by the Columbus Zoo 27 August 1985, and laid single eggs on 27 August, and 4 and 28 September 1985. The first of these, 46 x 51 mm, 26 g, hatched 7 February 1986 after 164 days incubation. The second, 45 x 30 mm, 23.7 g, hatched 4 February 1986 after 154 days incubation. The third, 41 x 24 mm, 25.5 g, failed to develop during incubation.

While laying dates for these three wild bred specimens fall within a 112 day period (3 August - 23 November), annual aspects of egg laying have not been clearly defined for the series laid in this collection. Clutches have been laid in all months except June and September, with single clutches in all months except December (2 clutches) and February (3 clutches). On five occasions, females have laid two clutches with internesting intervals of less than 150 days, including the period 13 November 1979 - 26 April 1980 during which the Detroit Zoo female laid 3 clutches with internesting intervals of 96 and 70 days.

Mean clutch size for the 14 clutches here reported has been 3.92 eggs per clutch, ranging from 2 to 7 eggs per clutch. Clutch size of only the 10 clutches in which hatching subsequently occurred has shown the extremes of this range, with a mean of 4.10 eggs per clutch. These figures include eggs broken during laying which are excluded from further data.

Eggs of the 14 clutches have ranged from 34 to 50 mm along the long axis (n=50, $\bar{X}$ = 42.09 mm), and from 24 to 32 mm along the short axis ($\bar{X}$ = 27.05 mm). Clutches which have included the extremes of both ranges have subsequently produced hatchlings. The 7 March 1985 clutch is noteworthy not only as the largest clutch (7 eggs), but also due to the small size of the eggs ($\bar{X}$ = 35.1 x 24.4 mm) and long incubation times of the two hatchlings (222 and 248 days). While one hatchling survived only 66 days posthatching, the remaining individual has appeared to be normal in growth and behavior since hatching (290 days).

Incubation periods have ranged from 140 to 248 days, with a mean (n=20) of 178.05 days. However, incubation periods within clutches have not varied more than 30 days (29 December 1985 clutch).

Hatchlings have ranged from 43 to 49 mm CL shortly after hatching and assumption of normal shell contour. Extended growth of specimens hatched in 1978 and 1980 is presented in Table II. Due to disparate hatching dates and dates of measure, ages are reduced

to years and days. Records are presented for 5 siblings, from 4 clutches. Other specimens from these clutches were removed from the collection shortly after hatching.

Of the two female progeny, the older (P.M. 1) consistently grew more slowly than a sibling hatched approximately 19 months later (P.M. 3), and laid her first clutch only 6 months before the first clutch laid by the younger animal. The earliest ages at egg laying for these were 6 years 116 days (187 mm CL) for P.M. 1, and 5 years 85 days (184 mm CL) for P.M. 3. Males (P.M. 4 and 5) were observed to be courting and attempting to copulate in the fall of 1984, in the early part of their fourth year. Clutches laid by sibling females (P.M. 1 and 3) were sired by one or the other of these males in their fourth year and subsequently. Presumably, clutches laid by the female obtained 25 January 1985 were also sired by one of these males.

Sexual dimorphism in tail length, preanal tail length, and preanal tail thickness is not so clearly defined in *P. gibbus* as in related forms. The most obviously dimorphic male of adults seen by the author (including but not limited to those here reported) has been the 1968 male in this collection. After 17 years in captivity, this specimen had a plastral length of 132 mm, a preanal tail length of 25 mm and tail length of 42 mm. The most obviously dimorphic female has had a plastral length of 170 mm, preanal tail length of 24 mm, and tail length of 42 mm. While the preanal tail of the male was greatly thickened, that of the female was only slightly so. No plastral concavities have been observed, and no dimorphism in the depth of the anal notch has been noted. Due to difficulties of obtaining accurate measurements of tail and preanal tail length in small living turtles no attempt has been made to quantify the onset of observable change in these external characters. However, observations on this series indicate that identification of sex based upon preanal tail length and

thickness is only fully applicable to specimens more than 3 years old, and of greater than 145 mm CL.

An incidental observation concerning *P. gibbus* concerns marking technique. As with other turtles in the Columbus Zoo collection, individuals are marked by scarring the plastral scutes with a rotary burr of appropriate size. In the period 1977 through 1985, in excess of 450 specimens of 48 forms have been marked with this technique, with resultant complications occurring in 6 animals. Five of these were *P. gibbus* which developed extensive necrosis, leading to death in 2 specimens. No explanation has yet become available for the dramatic difference in effect of this marking technique on *P. gibbus* as opposed to other forms.

TECHNIQUE

A METHOD FOR RAPID AND PRECISE DOCUMENTATION OF LIZARD COLORATION

Color patches of many iguanid lizard species are known to provide important signals during social interactions. The messages they convey have been and continue to be the focus of considerable work (Crews and Williams 1977; Ferguson 1976; Greenberg and Noble 1944; Hover 1985; Losos 1985; Sigmund 1983; Vinegar 1972; Williams and Rand 1977). In order to understand the social significance of color variation within and between populations or species it is necessary to accurately document the coloration under study.

Until recently, the tree lizard, *Urosaurus ornatus*, one of the most abundant lizards in the western U.S., had received little attention from ethologists. In both sexes, considerable color variation is known between and, sometimes, within populations (Murray 1953; Roueche 1971; Smith 1946). Males exhibit belly patches of varying intensities of blue or blue-green and throat patches that may be yellow, orange, green or blue, or some combination of these (Gates 1963; Hover 1985; Roueche 1971; Smith 1946; Thompson, pers. comm.; Zucker, pers. obs.). Females lack the blue belly patches but have variably-colored throats (Roueche 1971; Zucker, pers. obs.). Current studies are exploring the significance of throat color variation and involve classifying throat colors of individual animals (Hover 1985; Thompson, pers. comm.; Zucker, in prep.).

This communication explores several methods that have been used to document lizard coloration and proposes a procedure for quantifying coloration in species whose colors are not stable over time. I demonstrate the method by comparing two populations of tree lizards and show that throat patch coloration of males may change rather rapidly and significantly upon capture.

METHODS

During July, 1986, male *Urosaurus ornatus* were captured by noose, six from the Aguirre Spring Recreation Site on the east slope of the Organ Mountains, 25 air km E of Las Cruces, Doña Ana Co., NM, and six from the Doña Ana Mts., 25 air km NE of Las Cruces. Males at Aguirre Spring generally have blue-green throats. Those in the Doña Ana Mts. exhibit more variable coloration. Their throats may be solid yellow, rust, orange or green, but most commonly have a varying amount of green as a central spot surrounded by a rust or orange rim. For this study, only males with a rust or orange rim and green central spot were used.

Within 15 sec of capture I compared the throat of each male with a series of Munsell color chips (see below), and the notation which most closely matched was recorded. The lizard was held in my hands until one min after capture when a second comparison was recorded. It was then placed singly in a one gallon translucent plastic jar and withdrawn at five and at sixty min after capture for additional readings. Each lizard was transported to the laboratory in an individual jar. At 24 hours after capture the throat color was again compared to the color chips. The lizards were then placed individually in 76 liter aquaria containing a layer of sand and a rock and could not see other lizards. The tanks were lit with two 40 watt Vita-Lite® bulbs (Duro-Test Corp.; North Bergen, NJ); each rock was heated with a 60 watt incandescent bulb. After two hours in the tank with a heat lamp, a final reading was made. Since the lab room was located close to a building exit, all readings were made outdoors in direct sunlight within 15 sec of removal from the jar or aquarium. The ventral part of the male was held facing directly into the sun during all readings. Hue comparisons between the lizard coloration and Munsell chips should not, however, be affected by light level.

The Munsell System of Color Notation (Munsell Color; Baltimore, MD) is a standardized set of color chips which identifies three attributes of color: hue (portion of the spectrum), value (degree of lightness) and chroma (degree of saturation or grayness). There are ten major hues, each divided into ten hue steps and symbolized as a number (1-10) and initial(s) for the major hue. Values are placed on a scale of 0 (for black) to 10 (for white); chroma ranges from 0 for neutral gray to about 14 or 16 for the most vivid (strong or saturated) colors. For simplicity, I am only reporting here on hues, although value and chroma were also recorded.

Photography has also been used to document throat color. I determined the accuracy of this method by photographing the Munsell color chips in both sun and light shade with a 35 mm SLR camera using Kodacolor VRG ISO 100 print film, Kodachrome 64 slide film and Ektachrome 64 slide film. The prints were locally processed (PDQ One Hour Photo Finishing); the slides were processed by Kodak. The prints were compared directly with the color chips. The slides were compared with the Munsell chips outdoors in direct sun against a white background with the aid of a hand lens, and also on a projector using a Sylvania DDK 60 watt bulb. The same nine hues, which included oranges, yellows, green-yellow, green, blue-green and blues, were compared for all three film types under all conditions.

RESULTS AND DISCUSSION

The green to blue-green throat color of two of the six males from Aguirre Spring (males 3 and 4) changed 2 1/2 hue steps within one min of capture and three males (a, 2, 4) changed 5 hue steps within five min (Fig. 1). Changes in major hue occurred in five males after 60 min and in all

after 24 hours in captivity (Fig. 1). The addition of a heat lamp brought the throat colors closer to those at the time of capture, but four males (1, 2, 3, 5) were still 2 1/2 or more hue steps different (Fig. 1). The orange rim on the Doña Ana males was much more stable, never changing more than 5 hue steps (Fig. 2A). However, the green or green-yellow central spot changed within one minute of capture for five males (1, 2, 4, 5, 6), and in males 1, 2 and 6 totally disappeared after 24 hours, revealing orange underneath (Fig. 2B). Thus, the green is relatively unstable and appears to be superimposed upon an orange background, normally seen only as a rim. Four Doña Ana males (2, 4, 5, 6) had green patches that did not return to their original color after two hours under the heat lamp (Fig. 2B). I do not know whether longer exposure to the heat lamps would have returned the color of these lizards to field conditions. For both populations, values and chromas also varied somewhat from their original notation.

Photography proved to be a poor method for documenting coloration. The best overall match between photographs and color chips occurred with the Kodachrome 64 slide film shot in light shade and displayed on a projector. Six of the nine color chips were 2 1/2 hue steps off; the remainder matched well. Value and chroma were not evaluated. If photography is used, the accuracy of the color should be documented by comparison with a Munsell chart. Different film batches and processing laboratories may also be sources of variation.

The biological significance of the degree of color change reported here is still unknown. However, Ferguson (1976) found that a change of as little as 5 hue steps in the orange spotting on female collared lizards represents a significant change in reproductive condition (pre- versus post-ovulation) and probably functions as a social signal. Thus, I recommend that workers interested in the social significance of color pattern in tree lizards document color immediately upon capture, at least until the relative stability of the colors for the study population is determined. For laboratory studies which use heat lamps to bring out the colors, I would recommend that initially, immediate documentation of coloration be made in the field for later comparison under the lamps. Once it is determined how long it takes for color to return to normal under the lamps, further field recordings should not be necessary. These recommendations, I believe, should also be followed for studies of coloration in other species of lizards, at least until it is apparent that color changes over time do not take place.

The Munsell color chip method is quick and can be precisely interpreted by other researchers who have access to the charts; it has been used successfully by other lizard ethologists (Benes 1969;

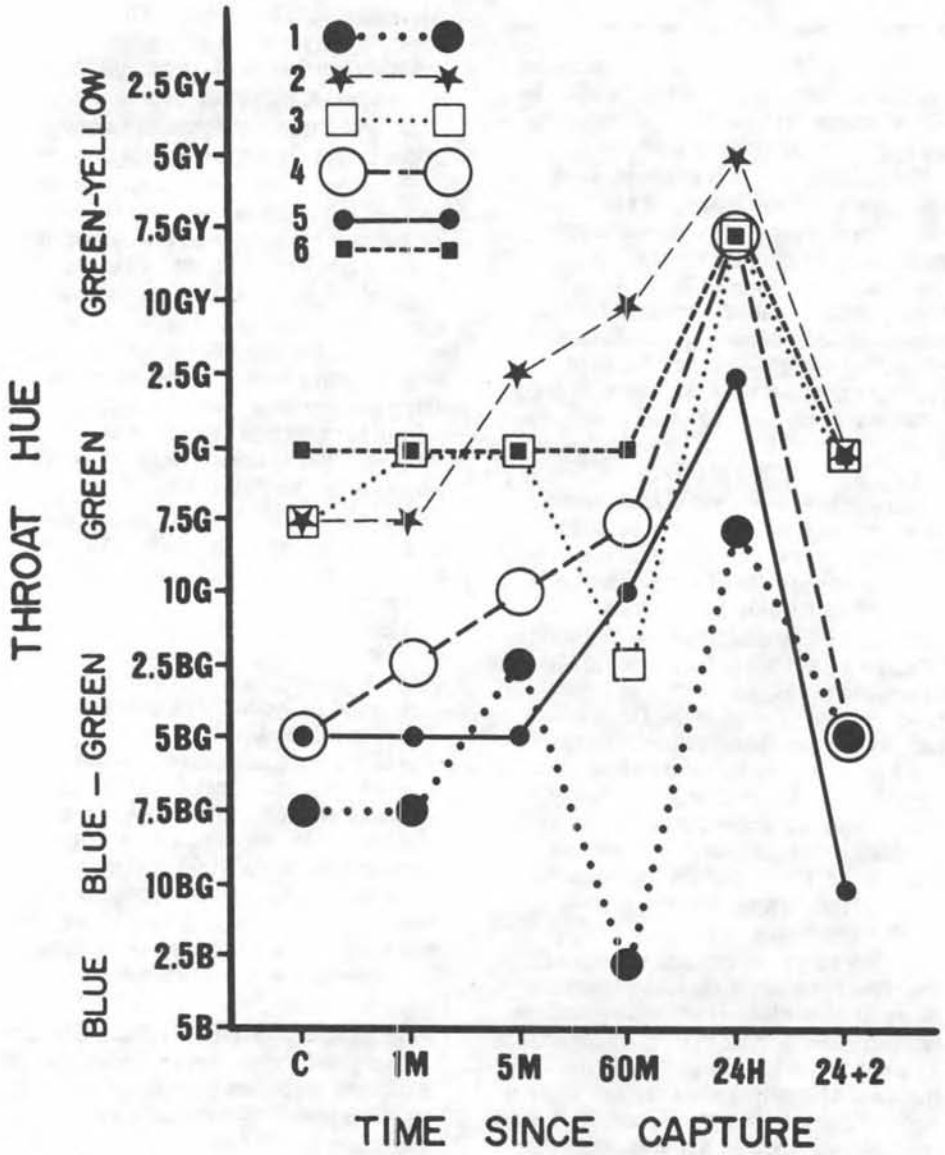

Figure 1. The throat color (Munsell hue) of six males from Aguirre Spring at the time of capture (C), and one min (1 M), five min (5 M), 60 min (60 M), 24 h (24 H) and 24 + 2 h under a heat lamp (24 + 2) after capture.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology. These geographic distribution records have a **standard format**, and all authors should adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (as it appears in **Standard Common and Current Scientific Names for North American Amphibians and Reptiles**, Second edition. Collins, Conant, Huheey, Knight, Rundquist and Smith, 1982), LOCALITY, (use **metric** for distances), DATE (day, month, year), COLLECTOR(S), VERIFICATION BY, PLACE OF DEPOSITION AND CATALOG NUMBER (required), COMMENTS, CITATION(S), SUBMITTED BY (give name and address in full — no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged). Photographs may substitute for a preserved specimen only when the live specimen could not be collected (*e.g.*, it was a protected species or it was found in a protected area). Photographs must be deposited in a university or museum collection, and the catalog number(s) provided.

Please submit new geographic distribution records, in the standard format only, to Alvin L. Braswell, North Carolina State Museum of Natural Sciences, P.O. Box 27647, Raleigh, North Carolina 27611-7647, USA. Short manuscripts are discouraged, and are only acceptable when data cannot be presented adequately in the standard format.

Recommended citation for new distribution records appearing in this section is: Jones, J. 1980. Geographic distribution: *Lampropeltis triangulum multistrata*. SSAR Herp. Review 10 (1):1.

A photograph by J.F.W. of first specimen, and short accompanying text by Anonymous, appear in the Delaware Conservationist 30(3):28, Fall 1987 , but no details on capture or biology are included. Choruses of one to ca. 30 individuals heard in a vernal pond surrounded by lowland shrubs and trees on several dates from 12 May to 20 June 1987. New state record. Population is ca. 232 km NNE of the northernmost portion of its known range in SE Virginia (Caldwell. 1982. *Hyla gratiosa*. Cat. Amer. Amphib. Rept.: 298.1-298.2), and 29.8 km N of a Caroline County, Maryland, locality where a single adult female was found on 18 June 1982 (Anderson, K. and H. G. Dowling 1982. Geographic Distribution: *Hyla gratiosa*. SSAR Herp. Review 13(4):130). These findings suggest that the Cape May County, New Jersey, population reported on by Black and Gosner (1958. Herpetologica 13(4):254-255) may be a natural population, and not introduced as they suggested.

Submitted by **RUDOLF G. ARNDT**, Faculty of Natural Sciences and Mathematics, Stockton State College, Pomona, New Jersey 08240, and **JAMES F. WHITE**, Delaware Nature Education Society, P.O. Box 700, Hockessin, DE 19707, USA

HYLA VERSICOLOR (Gray Treefrog). USA: WISCONSIN: Florence Co: Norbertine property along Morgan Lake (T38N, R16E, Sec 18). 11 June 1987. P.A. Cochran. Verified by P.A. Cochran. University of Wisconsin-Green Bay Richter Collection (0311-R). Calling male; SVL 54mm. New county record (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Pub. Mus. 205 pp.)

Submitted by **PHILIP A. COCHRAN**, Division of Natural Sciences, St. Norbert College, De Pere, WI 54115, USA

PACHYMEDUSA DACNICOLOR (Mexican Leaf-frog). Mexico: Sonora: Centro Acuicola de Esperanza: 10 km NE Ciudad Obregon. 11 October 1986. Adrian Quijada. Verified by Adrian Quijada. Herpetology Collection of Ecological Center of Sonora (0585). New record in riparian community of Foothills, Sonoran Desert subregion (Duellman, W. E. 1970.). Monogr. Mus. Nat. Hist. Univ. Kans. 1, Lawrence). Mexican Leaf frog found in association with *Bufo mazatlanensis* and *B. cognatus*.

Submitted by **ADRIAN QUIJADA**, Centro de Estudios Superiores del Estado de Sonora (CESUES). Escuela Superior de Ecología. Ley Federal del Trabajo, prolongación Col. Apolo, E.P. 83200, Hermosillo, Sonora, México

PTERNOHYLA FODIENS (Lowland Burrowing Treefrog). MEXICO: JALISCO La Huerta: Estación de Biología Chamela, 59 km NW Barra de Navidad. 1 October 1986. A. García and E. Pérez. Verified by G. Casas. Colección Herpetológica de la Estación de Biología, UNAM (EBCH 0302). Extends range to coastal Jalisco (Duellman 1970. Monogr. Mus. Nat. Hist. Univ. Kans. 1, Lawrence).

Submitted by **ANDRES GARCIA**, Estación de Biología Chamela, Instituto de Biología, UNAM. Ap. 21 San Patricio, Jalisco 48980 México and **EDMUNDO PEREZ**, Laboratorio de Herpetología, Departamento de Zoología, Instituto de Biología, UNAM. Ap. 70-153, México, D.F. 04510, México.

RANA PALUSTRIS (Pickerel Frog). USA: ARKANSAS; Marion Co.: 5.1 km S Oakland (T20N, R15W, S10). 25 April 1980. S.E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 8852). Clark Co.: 1.6 km W Arkadelphia T7S, R20W, S15). 24 September 1974. S.E. Trauth. (ASUMZ 8826). Hot Spring Co.: 1.8 km W Donaldson (T6S, R18W, S4). 4 April 1986. S.E. Trauth and P. Chaffin. All verified by S.E. Trauth. (ASUMZ 5676, 5699). New county records (Schaaf and Smith. 1971. Cat. Amer. Amph. Rept. 117.1-117.3).

HEMIDACTYLUS TURCICUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Dallas Co.: collected from an apartment complex. 1 August 1984. Aletha Jesttis. Verified by Thomas Vance. Deposited in the Navarro College Herpetological Collection (NC

Reptile Cages

FOR THE AMATEUR
OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16" thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door is inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24" Reptile Cage $33.95
24" Wide, 12-1/4" High, 12-1/2" Deep
250 sq. in. Floor Area, Single Vent

36" Reptile Cage $58.95
36" Wide, 18" High, 19" Deep
580 sq. in. Floor Area, Double Vent

Prices include freight charges and are shipped via UPS. Institutions, zoos and dealers are invited to write on letterhead for quantity prices.

1984.8. 1.1L). New county record of this introduced species (Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press. College Station, Texas).

Submitted by **MIKE CHEATHAM**, Rt. 1, Box 108, Milford, TX 76670, USA

HEMIDACTYLUS TURCICUS TURCICUS (Mediterranean Gecko). USA: TEXAS: Burnet Co: 9.7 km S and 6.4 km W Burnet, Longhorn Cavern State Park. 18 August 1987. M.S. Calaway. Verified by J.E. Cordes and J.M. Walker. University of Arkansas, Department of Zoology (UADZ 2574). The subsequent collection of an additional specimen, and the sighting of another Mediterranean gecko, suggest that a population has been established in the State Park. New county record (Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station xii + 434 pp.) extending margin of range northwestward from Travis county. Specimen collected under authority of Texas Parks and Wildlife permit No. 61 and State Park permit No. 20-87.

Submitted by **MICHAEL S. CALAWAY**, Longhorn Cavern State Park, Park Road 4, Burnet, Texas 78611, **JAMES E. CORDES** and **JAMES M. WALKER**, Department of Zoology, University of Arkansas, Fayetteville, AR 72701, USA

OPHISAURUS ATTENUATUS ATTENUATUS (Western Slender Glass Lizard). USA: ARKANSAS: Sharp Co: 12.6 km E Cave City (T15N, R4W, S16). 15 May 1987; 14.1 km E Cave City (T15N, R4W, S15). 20 May 1987. S.E. Trauth. Verified by S.E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 8010, 8060). New county record (Dowling 1957. Occ. Pap. Univ. Arkansas Mus. 3:1-51; Holman 1971. Cat. Amer. Amph. Rept. 111.1-111.3).

Submitted by **STANLEY E. TRAUTH**, Department of Biological Sciences, Arkansas State University, State University, AR 72467, USA

PODARCIS MURALIS (European Wall Lizard). USA: OHIO: Hamilton Co: Cincinnati Zoo and Botanical Garden. 2 May 1987. S.E. Hedeen. Verified by G.F. Petri. Xavier University (photo nos. 46Y1-46Y3). This second Cincinnati population was established in1985 by Children's Zoo escapees, originating from the population 4 km SW (Vigle 1977. SSAR Herp. Review 8(3) Supplement:19).

Submitted by **STANLEY F. HEDEEN**, Department of Biology, Xavier University, Cincinnati, OH 45207, USA

SCELOPORUS OCCIDENTALIS OCCIDENTALIS (Northwestern Fence Lizard). USA: WASHINGTON: Snohomish Co.: 5.3 km N, 4.7 km W of Tulalip (T30N, R4E, Sec 6 SW 1/4) elev. 915 m. 7 September 1986. T.C. Mathies. Verified by K.B. Aubry. University of Washington Burke Museum, Seattle (UWBM 2123). Northernmost record for eastern Puget Sound region, and first record for Snohomish Co. (Nussbaum et al. 1983. Amphibians and Reptiles of the Pacific Northwest. Univ. Press Idaho, 332 pp.).

Submitted by **THOMAS C. MATHIES**, Burke Museum, University of Washington, Seattle, WA 98195 and **KEITH B. AUBRY**, USDA Forest Service, Pacific Northwest Research Station, Olympia, WA 98502, USA

SERPENTES

AGKISTRODON PISCIVOROUS LEUCOSTOMA (Western Cottonmouth). USA: TEXAS: Navarro Co: 1 km W Kerens on Richland Creek. 9 October 1986. Chad Marion. Verified by Thomas Vance. Deposited in the Navarro College Herpetological Collection (NC 1986. 10.9.1S). New county record fills hiatus between Ellis, Henderson, Freestone, and Limestone Counties (Dixon, J. 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press. College Station, Texas; Vermersch, T. and R. Kuntz. I986. Snakes of South Central Texas. Eakin Press. Austin, Texas). USA.

Submitted by **MIKE CHEATHAM**, Rt. 1, Box 108, Milford, TX 76670, USA

CARPHOPHIS AMOENUS (Worm Snake). USA: OHIO: Hamilton Co: 4.8 km N, 3.2 km W Miamitown. 10 July 1985. D. Shaw. Verified by Robert S.

NATURE CONSERVATION

The Role of Remnants of Native Vegetation

Ed. D. SAUNDERS, G. ARNOLD A. BURBIDGE and A. HOPKINS

Over the world, clearing of land has removed most of the natural vegetation leaving small remnants of the original ecosystems. Areas that previously contained important biological resources have been amongst those cleared, so that many plant and animal species have become restricted to remnants, which may consequently hold a vital store of genetic material.

Price $U.S. 60.00

The book is divided into four main themes:

1. *Ecological studies as the basis of management;*
2. *Fragmentation and population genetics;*
3. *Measuring and monitoring dynamics of remnants; and*
4. *Management.*

Rept. 314.1-314.2).

Submitted by **STANLEY E. TRAUTH**, Department of Biological Sciences, Arkansas State University, State University, AR 72367, USA

HETERODON PLATYRHINOS (Eastern Hognose Snake). USA: WISCONSIN: Waupaca Co: Bestul Road, ca. 1 km N of State HWY 161, near Iola. (T24N, R12E, S34). 2 May 1987, G. Messinger. Verified by R.M. Korb. University of Wisconsin-Green Bay Richter Collection (0317-R). New county record (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Mus. 205 pp.).

Submitted by **RANDY M. KORB**, 1121 Emilie Street, Green Bay, WI 54301, USA

NERODIA FASCIATA FASCIATA (Banded Water Snake) USA: NORTH CAROLINA: Camden Co: 3.1 km E Elizabeth City [Pasquotank Co.]. 18 June 1976. R. G. Arndt et al. N. C. State Museum of Natural History (NCSM 18787); Hertford Co: near Harrellsville. 20 May 1977. O. Boody. (NCSM 17922); Pasquotank Co: 3.2 km from Perquimans Co. line, between Belvidere and Elizabeth City [= ca. 9 km WSW Elizabeth City]. 2 September 1962. N. Rothman. American Museum of Natural History (AMNH 89144); Perquimans Co: 5.6 km SW Belvidere. 10 May 1980 (NCSM 20896) and 18 May 1980 (NCSM 20902). J. P. Perry; Suttons Cr., 6.8 km ESE Hertford. 18 June 1979, J. P. Perry and A. L. Braswell. (NCSM 20163). All verified by R. Conant. Extends range north of Albemarle Sound (Conant 1963. Amer. Mus. Novitates, No. 2122:1-38).

Submitted by **WILLIAM M. PALMER** and **ALVIN L. BRASWELL**, North Carolina State Museum of Natural History, P.O. Box 27647, Raleigh, NC, USA

NERODIA RHOMBIFERA RHOMBIFERA (Diamondback Water Snake). USA: ARKANSAS: Marion Co: 5.4 km S. Oakland (T20N, R15W, S14). 24 July 1975. S. E. Trauth. Verified by Max A. Nickerson. Milwaukee Public Museum (MPM 20332). New county record that fills a distributional gap in the Ozark Mountains (McAllister 1985. Cat. Amer. Amph. Rept. 376.1-376.4).

Submitted by **STANLEY E. TRAUTH**, Department of Biological Sciences, Arkansas State University, State University, AR 72467, USA

REGINA SEPTEMVITTATA (Queen Snake). USA: ARKANSAS: Johnson Co: 2.1 km W Oark (T12N, R25W, S24). 23 July 1987. S.E. Trauth. Veried by S.E. Trauth. Arkansas State University Museum of Zoology (ASUMZ 8747). New county record (Dellinger and Black 1983. Occ. Pap. Univ. Arkansas Mus. 1:1-47; Dowling 1957. Occ. Pap. Univ. Arkansas Mus. 3:1-51; Schwardt 1938. Univ. Arkansas Agric. Exp. Sta. Bull. No. 357. 47p).

Submitted by **STANLEY E. TRAUTH**, Department of Biological Sciences, Arkansas State University, State University, AR 72467, USA

RHADINAEA FLAVILATA (Pine Woods Snake). USA: SOUTH CAROLINA: Aiken Co: 8.9 km SE of Jackson at Hwy 125, ca. 33°15'N, 81°44.5'W. 9 May 1987. David P. Young, Jr. and David J. Davis. Verified by J. Whitfield Gibbons and Trip Lamb. National Museum of Natural History (USNM 278317). New county record and first record for Savannah River Plant. Extends range of 112 km from coast to ca. 150 km (Myers 1974. Bull. Am. Mus. Nat. Hist. 153:49-54.). Also extends range ca. 145 km NW of closest previous records [South Carolina: Berkeley Co.: 8 mi W Moncks Corner (Carnegie Museum 28892-28893)]. Collected during studies under Contract DE-AC09-76SR00819 between the U.S. Department of Energy and the University of Georgia.

Submitted by **DAVID P. YOUNG, JR.**, Zoology Department, University of Georgia, Athens, GA 30602, USA

SISTRURUS MILIARIUS STRECKERI (Western Pigmy Rattlesnake). USA: TEXAS: Montague Co.: within Sunset city limits. 9 October 1987. D. Balentine. Verified by M.A. Nelson. University of Texas-Arlington Collection of Vertebrates (UTA R-19315).

New county record, extends range at least 16 km westward of Wise and Cooke County localities (Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press. College Station. i-xii + 434 pp.). *S. m. streckeri* appears to be restricted to more mesic habitats within the surrounding grasslands.

Submitted by **MARK A. NELSON**, Department of Biology, The University of Texas at Arlington, Arlington, TX 76019, USA

SISTRURUS MILIARIUS STRECKERI (Western Pigmy Rattlesnake). USA: ARKANSAS: Dallas Co: 4.8 km E Manning (T8S, R16W, S29). 28 September 1974; 12.8 km NW Fordyce (T10S, R14W, S5). 28 September 1974. S.E. Trauth. Arkansas State University Museum of Zoology (ASUM Z 8848-8849); Ouachita Co: 8.5 km N Amy (T11S, R17W, S11). 28 September 1974. S.E. Trauth. (ASUMZ 8846). All verified by S.E. Trauth. New county records (Palmer 1978. Cat. Amer. Amph. Rept. 220.1-220.2).

Submitted by **STANLEY E. TRAUTH**, Department of Biological Sciences, Arkansas State University, State University, AR 72467, USA

STORERIA DEKAYI TEXANA (Texas Brown Snake). USA: TEXAS: Llano Co: 20.8 km W Burnet on State Hwy 29. 28 April 1977. F.E. Cordes. Verified by J.E. Cordes and J.M. Walker. University of Arkansas, Department of Zoology (UADZ 2602). New county record (Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press. College Station xii + 434 pp.) filling hiatus between Burnet, San Saba, Mason and Gillespie counties.

Submitted by **JAMES E. CORDES**, Department of Zoology, University of Arkansas, Fayetteville, AR 72701, USA

STORERIA DEKAYI WRIGHTORUM (Midland Brown Snake) USA: ARKANSAS: Randolph Co: Jane's Creek (T19N, R1W, S17). 21 March 1987. Arkansas State Museum of Zoology (ASUMZ 6965). Independence Co: Salado Creek (T11N, 6W, 52). 24 March 1987. (ASUMZ 7604). Both collected by W.E. Meshaka Jr. Both verified by S.E. Trauth. New county records (Dowling 1957. Occ. Pap. Univ. Arkansas Mus. 3:1-51).

Submitted by **WALTER E. MESHAKA, JR.**, Department of Biological Sciences, Arkansas State University, State University, AR 72467, USA

TESTUDINES

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: NEW MEXICO: Socorro Co: La Joya State Game Refuge, (T1N, R1E). 24 May 1978. C.W. Painter. Verified by C.W. Painter and J.N. Stuart. Museum of Southwestern Biology, University of New Mexico (MSB 33590); Bernalillo Co: US Hwy 85 at Valencia Co. line, "Isleta Marsh," (T8N, R2E, Sec 34). 5 April 1987. J.N. Stuart. Verified by R.D. Jennings and J.N. Stuart. (MSB 48733). First specimens from Rio Grande drainage of New Mexico (Degenhardt and Christiansen 1974. Southwest. Nat. 19(1):21-46). More extensive distribution in drainage (Stebbins 1985. Field Guide to Western Reptiles and Amphibians, 2nd ed. Houghton Mifflin Co.) is unsubstantiated by specimens (R.C. Stebbins, pers. comm.).

Submitted by **JAMES N. STUART**, 516-#3 Columbia SE, Albuquerque, NM 87106, and **CHARLES W. PAINTER**, Endangered Species Program, New Mexico Department of Game and Fish, Villagra Building, Santa Fe, NM 87503, USA

CHRYSEMYS PICTA (Painted Turtle). USA: WISCONSIN: Florence Co.: on road from Fence to Morgan Lake (T38N, R16E, Sec 23). 8 Jume 1987. P.A. Cochran. Verified by P.A. Cochran. University of Wisconsin-Green Bay Richter Collection (0309-R). Shell fragments of road killed adult. New county record (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin. REPTILES
OF SOUTHERN AFRICA

AUTHOR: Rod Patterson PHOTOGRAPHY: Anthony Bannister

This is the first major work in FULL COLOR depicting southern Africa's most picturesque and often bizarre members of the reptilian clan. A section on snakebite & its treatment, plus the aspects of reptiles in captivity, makes this a superb and informative volume.

FORMAT: Hard cover, 8½ x 11½ inches, 128 pages of fact-filled information, and over 50,000 words of excellent text.

PHOTOS: **230 ALL-COLOR**, showing the animals in a variety of lively positions and not on a background of unrelated substrate.

Turtles & Tortoises laying eggs,
Lizards feeding and mating,
Snakes shedding, feeding and mating,
.... just to mention a few.

DISTRIBUTIONAL RECORDS FOR REPTILES AND AMPHIBIANS FROM THE PUERTO RICAN BANK

Field and museum studies of the biogeography of the Puerto Rican Bank, especially the Virgin Islands, have led to the discovery of several new island records for reptiles and amphibians. All specimens representing new island records are in the Museum of Comparative Zoology, Cambridge (MCZ) or the National Museum of Natural History, Washington (USNM). We also present new locality (not island) and morphological data for *Epicrates monensis granti*, a species rare in collections, and discuss the locality data of specimens in the American Museum of Natural History, New York (AMNH).

Although numerous herpetologists have visited the Virgin Islands (for previous records see Schwartz and Thomas 1975; Schwartz et al. 1978; Philibosian and Yntema 1976, 1978; MacLean et al. 1977; and Lazell 1983), we suspect that a number of islands harbor more species than are currently known. The species-by-island occurrence matrix for these islands is quite "nested" (Diamond and Gilpin 1982); i.e., the species list of each island tends to be a subset of that of the next larger island, and the island list of each species tends to be a subset of that of the next more widely distributed species. This regular pattern of distribution can be clearly seen in Lazell's (1983) Table 1. If the matrix were perfectly nested, each species would occur on all islands above a threshold size for that species; and, each island would be inhabited by all species occurring on islands smaller than it in size, plus additional species found only on islands of that size and larger. Assuming that future collecting will conform to this pattern, making the matrix more nearly perfectly nested, allows prediction of what species will be found on which islands. Distributional gaps may be most easily seen by looking at Table 1 of Lazell (1983), and noting the lacunae in the otherwise densely occupied upper and left hand portions of the matrix. That these predictions can be useful is borne out by the fact that as we compiled literature records for the Puerto Rican Bank, the initial nested pattern became more perfect as further sources were examined (a form of "retrodiction"), and that collecting efforts guided by these predictions have turned up expected species.

Particularly noteworthy in this regard is Jost van Dyke, which, for an island of its size (840 ha), is lacking a number of species. Most surprising is the absence of *Ameiva exsul*, a species otherwise found on every one of the British Virgins greater than 24 ha (except Great Thatch, 187 ha), and known from the much smaller and closely adjacent island of Little Jost van Dyke. During a day-long visit to Jost van Dyke we recorded two expected species there for the first time, but failed to find *Ameiva*, or another expected species, *Liophis (= Alsophis) portoricensis*. The reason for the absence of these two species was explained to us by a number of residents. Some seven to ten years previously, a resident of the island released mongooses *(Herpestes auropunctatus)* in hopes of wiping out snakes, which, he feared, might discomfort tourists. The mongoose, a number of which were seen during our brief visit, has apparently been effective. Our informants agreed that it was responsible for the disappearance of the ground lizard *(Ameiva)* and the common snake *(Liophis)*, both of which they were familiar with. They had not seen snakes for a few years, but ground lizards were seen occasionally. One person, familiar with the extant fauna, said he had seen a lizard about 2½ months prior to our visit.

NEW RECORDS

Eleutherodactylus lentus: U.S.V.I.: HASSEL ISLAND. 12 April 1932. C. M. Grant. (MCZ 18776). This island was part of the mainland of St. Thomas until 1865, when a channel was dug connecting St. Thomas Harbor and Gregerie Channel (Gjessing, 1980-1981).

Eleutherodactylus antillensis: B.V.I.: FRENCHMAN'S CAY. 3 April 1982. C. Stoner (MCZ 107344). B.V.I.: GUANA ISLAND. 8 November 1984. T. Giovannone. (MCZ 107528). These are the two smallest (24 and 297 ha, respectively) islands in the British Virgins inhabited by *Eleutherodactylus*.

Hemidactylus mabouia: B.V.I.: JOST VAN DYKE: Great Harbour. 24 July 1984. G. C. Mayer and J. D. Lazell. (MCZ 170885-86). This species was listed from Jost van Dyke by Heatwole et al. (1981) as an unverified literature record. We have not found the prior literature reference, but confirm the species' presence on the island with two juveniles collected from under boards during daylight. Island residents are familiar with the species. B.V.I.: FRENCHMAN'S CAY. 3 April 1984. J. D. Lazell. (MCZ 166967). B.V.I.: BELLAMY CAY. 24 July 1985. G. C. Mayer and E. M. Azevedo. (MCZ 170887).

Sphaerodactylus macrolepis: B.V.I.: CARROT ROCK: Sloane Ghut. 13 July 1985. J. D. Lazell. (MCZ 170890).

Sphaerodactylus parthenopion: B.V.I.: TORTOLA: Zion Hill, ca. 150 m N of jct. with south coast road. 13 June 1980. R. Crombie and G. Pregill. Verified by W. P. MacLean. (USNM 221593).

Anolis cristatellus: PUERTO RICO: ISLA DE CABRAS (= LEPER ISLAND), near San Juan. 7 December 1931. C. Grant. (MCZ 35753). PUERTO RICO: PUNTA SALINAS ISLAND, west of San Juan. January 1932. C. Grant. (MCZ 35929-30). PUERTO RICO: CAYO RATONES, near Jobos. February 1932. C. Grant. (MCZ 35776-85). B.V.I.: SKIPPER CAY, an otherwise nameless cay south of Key Point, Peter Island; cay #1 of Lazell 1983. 13 July 1985. G. C. Mayer and J. D. Lazell. (MCZ 170894-7).

Anolis pulchellus: PUERTO RICO: ISLA DE CABRAS (= LEPER ISLAND), near San Juan. 7 December 1931. C. Grant. (MCZ 36089). B.V.I.: FRENCHMAN'S CAY: Meown, the Dupont-Dean estate at far west end of island. 8 July 1985. G. C. Mayer and N. Stokes. (MCZ 170891).

Anolis stratulus: B.V.I.: FRENCHMAN'S CAY: Meown, the Dupont-Dean estate at far west end of island. 8 July 1985. G. C. Mayer and N. Stokes. (MCZ 170893).

Ameiva wetmorei: PUERTO RICO: ISLA MORRILLITO (= PLATILLO). May 1932. C. M. Grant. (MCZ 36429). The locality is recorded in the MCZ catalogue as "Islet S. of Caja de Muertos Id." This could only refer to Isla Morrillito (see USGS map N1752.5-W6630/7.5, Playa de Ponce quadrangle), also known as Platillo (Schwartz and Thomas, 1975). A second specimen from Isla Morrillito (MCZ 36430) was exchanged to the Museu de Zoologia de Universidade de Sao Paulo. Both specimens are paratypes of *Ameiva wetmorei eleanorae* Grant and Roosevelt, 1932.

Mabuya mabouya sloanii: B.V.I.: GUANA ISLAND. 13 July 1984. G. C. Mayer and J. D. Lazell. (MCZ 166975); 21 October 1984. P. Shelby. (MCZ 170883). B.V.I.: CARROT ROCK: Sloane Ghut. 13 July 1985. J. D. Lazell. (MCZ 170884).

Amphisbaena fenestrata: B.V.I.: GUANA ISLAND. 9 March 1984. J. D. Lazell. (MCZ 166995); 7 November 1984. T. Giovannone.

(MCZ 170889).
Typhlops richardi: B.V.I.: JOST VAN DYKE: Great Harbour. 24 July 1984. G. C. Mayer and M. Gibbons. (MCZ 170892). B.V.I.: GUANA ISLAND. Various dates from March 1982 to November 1984. G. Durrell, J. D. Lazell, L. Jarecki, D. Ford and M. Gibbons. (MCZ 166937-38, 166954, 166980-85).
Epicrates monensis granti: U.S.V.I.: ST. THOMAS: 2V7 Estate Nazareth. January 1984. R. Olive. (MCZ 166976). B.V.I.: TORTOLA: Pockwood Pond. November 1983. N. Grigg. (MCZ 166977). The St. Thomas specimen comes from the eastern end of the island, as do all previous specimens from this island (Nellis et al. 1984). The Tortola specimen is the second recorded from that island, and the first with specific locality data. Mr. Richard Starkey reported seeing boas in his rafters three times in two years at Havers, near Pockwood Pond on Tortola. All specimens and reports of this species with precise locality from Tortola thus seem to come from the more arid parts of the island, west of Road Town. This agrees with Nellis et al.'s finding that the species occurs in the more arid eastern part of St. Thomas.

Since only five specimens were available to Sheplan and Schwartz (1974) in the most recent treatment of this form, we provide in Table 1 morphological data for these two specimens. Sheplan and Schwartz found that the previously known Tortola specimen (the holotype) had the highest number of ventrals and dorsals. The present specimen extends the upper limits for ventrals, subcaudals and midbody dorsals, supporting their suggestion that the Tortola population may prove differentiable from that of St. Thomas. The St. Thomas specimen extends the upper limit of number of tail blotches.

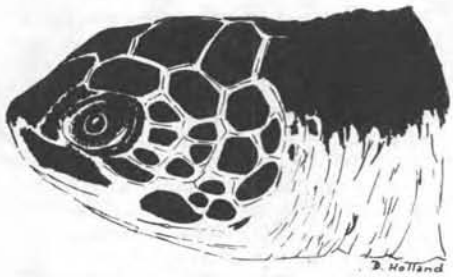
There are some discrepancies between Nellis et al. (1984) and Lazell (1983) regarding the islands on which this species occurs. The following is the basis for records of this species. Museum specimens exist for Tortola and St. Thomas. The record for Guana Island is based on Grant (1932), and supported by descriptions of the morphology and behavior of a snake killed by residents a few years ago. Necker Island and Virgin Gorda are sight records by Dr. John G.H. Smith of Road Town, Tortola, a botanist. Cayo Diablo is a sight record by Richard Thomas (Nellis et al. 1984). For Great Camanoe, a specimen exists and is in the possession of a local resident. A snake very much like the boa has been described to us by Mr. F. Collwood from Jost van Dyke, who kept the specimen for a while in formaldehyde, but it has now apparently been lost.
Liophis (= Alsophis) portoricensis anegadae: B.V.I: GREAT CAMANOE. 11 March 1984. L. Jarecki and J. D. Lazell. (MCZ 166965-66). This is by far the most common snake in the British Virgins; in contrast, *Liophis (= Arrhyton) exiguus* is the common species in the U.S. Virgin Islands (MacLean 1982).

Table 1. Morphological data for *Epicrates monensis granti.* In the first column, the first two rows give MCZ numbers, and the third and fourth rows give lower and upper limits, respectively, from Sheplan and Schwartz (1974). Lengths in millimeters.

	Sex	SVL	Tail Length	Ventrals	Sub-caudals	Dorsals	Body Blotches	Tail Blotches
166976	♀	602	142	263	84	38/43/24	67	23
166977	♂	479	120	271	90	36/48/26	65	22
low				261	80	34/41/23	61	20
high		770		269	84	38/47/31	73	22

ERRONEOUS RECORDS

Anolis pulchellus: U.S.V.I.: ST. CROIX: Christiansted. 5 March 1919. A. Emerson. (AMNH 14051). This species is otherwise unknown from St. Croix, which, though politically part of the Virgin Islands, is on its own island bank separated by deep water from the Puerto Rican Bank, on which all the other Virgins lie. The expedition which collected the specimen had been in St. Thomas the day before, and the specimen's field number is shared with specimens from that island. Although the possibility of human introduction, or even an ill fated natural colonization cannot be ruled out, it is most likely that the locality data became confused.
Anolis sagrei: "PORTO RICO". 1906. W. M. Wheeler. (AMNH 1614). This species is native to Cuba, the Bahamas and several other islands and mainlands in the northwestern Caribbean; it is almost certainly erroneously recorded from Puerto Rico.



ACKNOWLEDGMENTS

We thank E. and W. P. MacLean for supplying valuable information, C. Crumly and E. E. Williams for reading the manuscript, R. Crombie for allowing us to report on a specimen he collected, and the many people who assisted with collecting in the field. Our work was funded by the Conservation Agency through a grant from the Mocatta Metals Corp.

NEW SECTION EDITOR FOR GEOGRAPHIC DISTRIBUTION

Herpetological Review welcomes Alvin Braswell as section editor for Geographic Distribution notes. Mr. Braswell, Curator of Lower Vertebrates at the North Carolina State Museum of Natural Sciences, begins his tenure with this issue. Correspondence concerning Geographic Distribution should be sent to him at the address listed in the preamble to this section.

We are grateful to Ellen Censky of the Section of Amphibians and Reptiles, Carnegie Museum of Natural History, for her excellent work as section editor during the past several years. ●

HERPETOLOGICAL REVIEW EDITORIAL POLICY

The following statement-of-purpose appeared in the Introduction to the first issue of **Herpetological Review** in 1967 (Corson Hirschfeld, Editor):

> "**Herpetological Review** incorporates the Ohio Herpetological Society Newsletter. Its primary function, as the name states, will be to review herpetology, past and present, in terms of the individuals, institutions, literature and other components of the field. Perhaps equally important, the **Review** will provide a unique means of communication among persons interested in amphibians and reptiles. We believe it will be of interest to all persons in herpetology and we hope all members will find it informative and entertaining."

Herpetological Review still remains true to that purpose. We will continue to publish semi- and non-technical articles (original research should be submitted to the **Journal of Herpetology**—see inside front cover for address), book reviews, institutional and regional society news, research requests of SSAR members, letters from readers directed to the field of herpetology, illustrations, and photographs. Manuscripts submitted must be typed, double-spaced, on 8½ X 11 paper, and should be sent in duplicate. Unpublished photographs of an unusual nature or of uncommon amphibians and reptiles may also be submitted. Submissions should be black-and-white 8 X 10, glossy prints, and should be accompanied by a descriptive caption. The name and address of the contributor should be taped or penciled on the back of each print. Return of photographs cannot be guaranteed unless adequate return postage is provided. Unused photographs which the editors have requested to examine will be returned at our cost.

Reprints of contributions cannot be supplied. Contributors may reproduce up to 200 copies of pages containing their own articles for private distribution only. No reproduction for sale purposes is permitted. **Herpetological Review** will accept commercial advertising (except live animal ads). Rates and copy information are available from the advertising manager.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

Membership is open to anyone interested in amphibians and reptiles. Members have voting privileges in the Society. They receive the **Journal of Herpetology** (four issues per year), **Herpetological Review** (four issues per year), and occasional issues of **Facsimile Reprints in Herpetology.** Members may purchase other Society publications at reduced rates.

ANNUAL DUES 1987

Student member	$20.00*	Sustaining member	$50.00*
Regular member	$27.00*	Contributing member	$75.00*
Institutional	$50.00*		

Make checks payable to SSAR. A receipt will be sent only upon request. Payment in U.S. funds only. Non-U.S. members please remit in U.S. dollars only by either International Money Order, draft on a U.S. bank, or by MasterCard or Visa (include account number and expiration date of credit card).

*All memberships and subscriptions *outside of the U.S.* require either a $5 surcharge to defray additional surface mailing costs or $25 for air mail delivery.

Subscriptions to **Herpetological Review** only are available for $10 per year. Subscriptions *outside of the U.S.* require a surcharge of $2.50 (surface) or $12.50 (air mail). Subscribers to **HR** only are not members of the Society.

Individuals are encouraged to join at the higher membership categories. Money from such support substantially helps promote the publications and services of the SSAR. For information about SSAR membership, write to:

Henri C. Seibert

Herpetological Review

Volume 18 December 1987 Number 4

30th ANNUAL MEETING HELD AT HOTEL MOCAMBO, VERACRUZ, VER., MEXICO

The 1987 Annual Meeting of the Society for the Study of Amphibians and Reptiles was held jointly with the Herpetologists' League in Veracruz, Ver. Mexico, 9-14 August. Local Committee Co-Chairmen Richard C. Vogt, Gustavo Casas-Andreu, and Zeferino Uribe hosted a very relaxed, diversified, and informative gathering of herpetologists from around the world at the Hotel Mocambo.

Board of Directors' Meeting

The annual meeting of the SSAR Board of Directors was held on Sunday, 9 August, under the chairmanship of SSAR President Norman J. Scott, Jr. Most Board members were present plus other officers, editors, committee chairs, and guests. The Board met for 8 hours and discussed annual reports submitted by each Society officer, editor, committee chair, and coordinator. The financial status of the Society was felt to be decidedly more secure than last year, and we have significantly reduced our deficit without any need or plans to increase dues. More remains to be done to eliminate the deficit, and Society editors are totally committed to carefully remaining within their budget allocations. Decisions of the Board were announced at the annual Business Meeting of the Society and are described in the following paragraphs.

Business Meeting

A. Call to Order

President Norman J. Scott Jr. called the 1987 business meeting of the Society for the Study of Amphibians and Reptiles to order at 1800 hr on Wednesday, 12 August, in room B of the Hotel Mocambo.

B. President's Report

President Scott announced the Society's deficit reduction plan, and stated that there was no necessity to increase dues. He also stated the commitment of officers and editors to total deficit elimination, and the eventual full restoration of programs curtailed when the Society altered its fiscal year in 1986. He then introduced other officers and editors, or their substitutes, to present reports.

C. Secretary's Report

Acting Secretary George Pisani summarized the report, indicating that the Board had, via mail ballot in the past year, approved the Society's Financial Exigency Guidelines, and also several measures aimed at restricting budget over-runs by the Society's various editors and others with fiscal responsibilities.

D. Treasurer's Report

Treasurer Henri Siebert reaffirmed that there would be no dues increase, and said that the Society is in considerably better shape than this time last year. He said that the Regional Society Affiliate Membership Program had added 42 new members to our ranks, and that 21 persons had taken Life Memberships; he hoped that these trends would continue. He said that the funding level of major Society programs had been somewhat restored, and that this should continue to catch up.

E. Publications Secretary's Report

Kraig Adler, representing Publications Secretary Douglas Taylor, reported that sales from Taylor's office were good, and that this revenue was a major factor in our deficit reduction. There were 102 prepublication orders for *Biologia Centrali-Americana, Reptilia & Batrachia*. The Board was considering reprinting various back issues of society publications, when necessary, at a shop which promised greatly reduced costs. The trade-off was that much scheduling flexibility was needed for printing, but this should not be a problem with back issues.

F. Editors' Reports

1. *Contributions to Herpetology*

Editor Kraig Adler announced that prepublication orders for Number 3 in the *Contributions to Herpetology* series, Jay Savage and Jaime Villa's *Introduction to the Herpetofauna of Costa Rica*, had accounted for about half the press order. Number 4 in the *Contributions to Herpetology* series, *Salamanders of China* by Zhao Ermi and Hu Qxiong, will be published early in 1988. Donations had been received to cover the cost of four color plates. Number 5, Gloyd and Conant's *Snakes of the* Agkistrodon *Complex*, was progressing well, with publication expected in 1989.

2. *Facsimile Reprints in Herpetology*

Editor Kraig Adler announced that *Biologia Centrali-Americana, Reptilia & Batrachia*, will appear in September 1987. Thanks to the generous donations of Ernie Liner, many other individuals, and regional societies, there will be 12 full color plates in the volume. In 1988, the series plans to publish a reprint of Bogert and Del Campo's book *Gila Monster and its Allies* (1956).

3. *Catalogue of American Amphibians and Reptiles*

Editor Jaime Villa announced that the *Catalogue* is on schedule for 1988, and in fact had a three year backlog of accounts. This means that subscribers will receive at least 20 accounts per installment. The comprehensive index is in preparation, with the Caudata and Salientia sections currently in review. Villa presented an informative introduction to desk-top publishing techniques, and indicated how this has been a great asset to SSAR in production of the *Catalogue* for considerably reduced costs. Villa closed by honoring C. J. McCoy with a plaque commemorating his 20-year editorship of the Lacertilia section of the *Catalogue*. McCoy is resigning this position at the close of 1987.

4. *Journal of Herpetology*

Editor Rodolfo Ruibal indicated that the Board had given the *Journal of Herpetology* a budget increase for 1988, and that this would allow the *Journal* to increase slightly the pagination in Volume 22. Louis Guillette, Jr. has replaced Paul Hertz as Associate Editor; David Chiszar and David Crews have been appointed to the Editorial Board.

5. *Herpetological Review*

George Pisani, reporting for Editor Martin Rosenberg, stated that advertising income has risen 31%, and *Herpetological Review* editors are investigating using desktop publishing techniques as a way to increase pagination in the 1988 volume at no increase in cost. This change should allow rapid reduction of the three-year backlog of feature articles, and also should allow resumption of all sections in each issue instead of in alternate issues as now is done. The addition of color to *HR* had been funded by increasing advertising rates. Plans to publish the Cumulative Index have been put on "hold" until manuscript publication has caught up with supply.

6. *Herpetological Circulars*

Number 16 (*Herpetological Collecting and Collections Management*) will be advertised this Fall. The next title in the series is *An Annotated Field List and Guide to the Amphibians and Reptiles of Monteverde, Costa Rica.*

G. Committee Reports

1. Conservation Committee

President Scott called Committee Chair Bill Brown to the lectern. Brown summarized the Committee's work during the year by reporting that *Pseudemys alabamensis* had been federally listed as Threatened, as had the western populations of *Gopherus polyphemus*. The Committee had not supported listing *Trachemys scripta elegans* in CITES Appendix II, and this had not been done. The Committee's recommendation that the proposed Stacy Dam project (Texas) be halted because of its severe impact on habitat of the Threatened Concho Watersnake (*Nerodia harteri paucimaculata*) had been disregarded by the Corps of Engineers and the US Fish and Wildlife Service. A subcommittee chaired by Tom R. Johnson had compiled a list of monetary values for amphibians killed in environmental accidents. The document is comparable to one which has already been prepared for fishes. Two resolutions would be presented as joint SSAR and HL resolutions at the closing banquet. They support acquisition and conservation of sea turtle nesting beaches by the State of Florida, and a call for the Georgia legislature to prohibit gassing of gopher tortoise burrows as a means of removing venomous snakes.

2. Meeting Sites Committee

President Scott announced that SSAR has accepted an invitation from the University of Michigan to participate in a three-way meeting of SSAR, the Herpetologists' League, and the American Society of Ichthyologists and Herpetologists in Ann Arbor in 1988. Dates for the meeting are 23-28 June, with field trips scheduled for the 29th. The Society's 1989 annual meeting will be held in conjunction with the World Congress of Herpetology.

3. Grants-in-Herpetology

Dale Belcher announced the Grants-in-Herpetology awards for 1987. **Graduate Student Herpetological Research:** John W. Beck, Jr. (University of Miami) "An investigation of the apparent competitive exclusion or reduction of the native Green Anole *Anolis carolinensis* by the introduced Brown Anole *Anolis sagrei* in nonwetlands habitat in southern Florida;" and Diana K. Hews (University of Texas at Austin) "Experimental analysis of resource defense, sexual selection and the potential evolution of phenotypic traits in a terrestrial lizard." Because of budget restrictions for 1987, this was the only category in which awards were made. The amount budgeted for 1988 awards has been increased, and the Chairman encouraged donations to this Society program.

4. Kennedy Award

Chairman J. Eric Juterbock announced that Mark P. Hayes (US Fish and Wildlife Service) and Mark R. Jennings (University of Arizona, Tucson) had been chosen as the winners of the 1987 Kennedy Award. Their article on decline of ranid frog species was chosen as the best student authored paper or note published in the *Journal of Herpetology*. Three papers and four notes were considered by the Committee.

5. Nominating Committee

Nominating Committee Chair Kraig Adler presented the following candidates for Society office in 1988; the slate had been approved by the Board of Directors. **President-Elect:** Richard R. Montanucci and Henri Siebert. **Secretary:** James S. Jacob (unopposed). **Treasurer:** Douglas H. Taylor (unopposed). **Director (Regular, USA):** J. Eric Juterbock and Ernest A. Liner. **Director (Regional Society Representative):** Harold DeLisle and Martin J. Rosenberg. President Scott called for nominations from the floor. No further nominations were made and George Pisani moved that nominations cease. The motion was seconded by Dale Belcher and approved by a voice vote. A ballot will be sent to all active members by first-class mail.

6. Resolutions

Whereas Georgia Game and Fish Law 27-1-30 makes it unlawful to use chemicals, devices or smokers of any kind in order to drive wildlife from dens, holes, or their other homes, "... provided that this Code section shall not apply to poisonous snakes"; and,

Whereas research on the effects of "gassing" gopher tortoise burrows has shown the practice to be harmful to protected species such as the gopher tortoise, eastern indigo snake and other regular inhabitants of tortoise burrows, and is nonselective for poisonous snakes; and,

Whereas most persons who "gas" and excavate tortoise burrows to drive out poisonous snakes do not have the expertise or means to determine whether poisonous snakes are the sole inhabitants or whether they cohabit the tortoise burrow with protected species; and,

Whereas federal and other state fish and wildlife agencies with jurisdiction over gopher tortoises and their habitats have recognized these facts by banning the practice of "gassing" and excavating tortoise burrows to remove poisonous snakes; therefore,

Be it resolved that the Society for the Study of Amphibians and Reptiles and the Herpetologists' League at their joint annual meeting for 1987 in Veracruz, Mexico respectfully urge the Georgia Department of Natural Resources to remove the exemption allowing the use of chemicals to remove poisonous snakes from burrows.

Be it further resolved that copies of this resolution be sent to the Commissioner of the Georgia Department of Natural Resources, the Executive Director of the Georgia Conservancy, Inc., and the President of the Georgia Wildlife Federation.

Whereas the loggerhead sea turtle (*Caretta caretta*) is a federally protected "Threatened" species in the USA, and the Florida population of the green turtle (*Chelonia mydas*) is federally classed as "Endangered," and,

Whereas some of the most important nesting habitat for these species in the Western Hemisphere, collectively known as "Brevard Turtle Beaches" and "Wabasso Beach," additionally provide critical habitat for the gopher tortoise (*Gopherus Polyphemus*), the eastern indigo snake (*Drymarchon corais couperi*) and the leatherback turtle (*Dermochelys coriacea*); and,

Special Pre-publication Offer

Middle American Herpetology

A Bibliographic Checklist

Jaime Villa, Larry David Wilson, and Jerry D. Johnson

Middle American Herpetology provides easy and quick access to the current knowledge on the composition and distribution of all species of amphibians and reptiles occurring between the Isthmus of Tehuantepec and Colombia.

May 128 pages
91 color and 20 b&w illus.
List Price **$35.00**

Special pre-pub price **$28.00**
Offer expires April 30, 1988

Orders should be sent to:
University of Missouri Press
200 Lewis Hall
Columbia, MO 65211

All major credit cards accepted

Whereas these beaches and adjacent habitats have been proposed for acquisition by Florida's Conservation and Recreation Lands Program to preserve them from the threats of development or agriculture, which have extensively destroyed similar habitats worldwide; therefore,

Be it resolved that the Society for the Study of Amphibians and Reptiles and the Herpetologists' League give their highest endorsement of the conservation of these lands, and encourage the CARLS Program to give highest priority to the preservation of these lands and the fauna and flora dependent upon them.

Whereas the Society for the Study of Amphibians and Reptiles and the Herpetologists' League were most distressed at the serious medical condition which has struck Local Committee member Ruebén Castro Franco; therefore,

Be it resolved that said societies sincerely wish Sr. Franco a speedy and complete recovery.

Be it further resolved that said societies similarly wish Ms. Dawn Wilson speedy recovery from her operation.

Whereas the Society for the Study of Amphibians and Reptiles and the Herpetologists' League have held their first non-USA annual meeting in Veracruz, Mexico; and,

Whereas several hundred intrepid herpetologists and their guests elected to brave the rigors of microbial succession and overexposure to excellent cuisine, archaeological adventures and other field trips, sun, sand, and cool breezes—and, oh yes, also paper sessions; and,

Whereas these assembled persons have had a splendid and productive time in Mexico; therefore,

Be it resolved that the Society for the Study of Amphibians and Reptiles and the Herpetologists' League jointly express their most sincere thanks and appreciation to Richard C. Vogt, Gustavo Casas-Andreu and Zeferino Uribe, our hosts; to the Instituto de Biologia de la UNAM and the Comité Nacional de Herpetologia, institutional sponsors of this meeting; to all members of subcommittees who have worked so hard, especially Claudia López C. and Elisabeth Arevalo, who have taken extra time to assist those of us illiterate in Spanish; and to the fine staff of Hotel Mocambo for their excellent service throughout this event.

Whereas several persons have generously given their time and effort to advance the goals of the Society for the Study of Amphibians and Reptiles during 1986; and,

Whereas the Society hopes that by lauding them here it may encourage them to do so again at some future time; therefore,

Be it resolved that the Society for the Study of Amphibians and Reptiles expresses its most sincere thanks to the following individuals:
Sherman A. Minton, President
George R. Pisani, Immediate Past President
Timothy R. Halliday, Director
Alan H. Savitzky, Director
Stephen G. Tilley, Editor, *Catalogue of American Amphibians and Reptiles*
Hugh R. Quinn, Chair, Nominating Committee
Richard A. Sajdak, Chair, Zoo Liaison Committee
Ray E. Ashton, Jr., Chair, Regional Society Liaison Committee

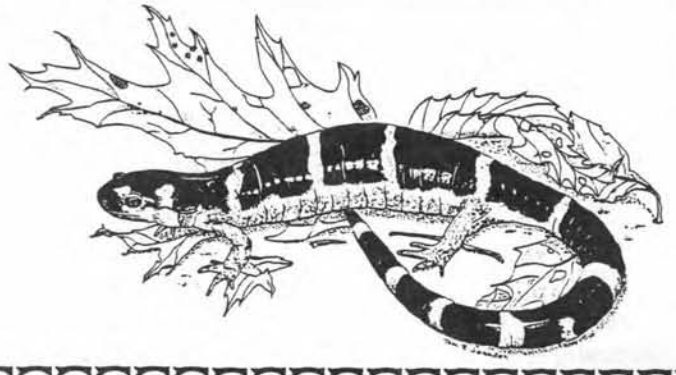
H. Transfer of Gavel and Adjournment: President Scott asked if there was any further business. There being none, Scott asked President-Elect Quinn to come forward and accept the SSAR gavel as a symbol of the transfer of the Presidency which will officially take place on 1 January 1988. Quinn thanked Scott, and moved (George Pisani seconded) that the meeting be adjourned. The motion passed by voice vote, and President-Elect Quinn declared the meeting closed at 1845 hr.

Respectfully submitted,
George R. Pisani
Assistant Secretary ●

Announcing a New Book . . .

The long awaited book on the amphibians and reptiles of Missouri is now available. *The Amphibians and Reptiles of Missouri* contains up-to-date information on the identification, distribution, natural history and status of the 107 species of amphibians and reptiles native to Missouri. The book contains 368 pages, 258 color photos, 109 maps, keys to adult amphibians and reptiles, a guide to selected tadpoles and an extensive bibliography. This will be a welcome addition to anyone's library.

The Amphibians and Reptiles of Missouri is authored by Tom R. Johnson, herpetologist for the state of Missouri and published by the Missouri Department of Conservation (1987).



To Order:

Soft cover edition ..... $13.00 (plus $.81 sales tax for Missouri residents)

Hard cover edition ..... $16.00 (plus $1.00 sales tax for Missouri residents)

Send order and payment to:
Missouri Reptile Book
Missouri Department of Conservation
P.O. Box 180
Jefferson City, Missouri USA
65102-0180

Payment for all foreign orders must be in U.S. currency. Make check or money order payable to: Missouri Department of Conservation. Prices include postage for orders within the U.S.; Canadian and Mexican orders add $3.92. All other foreign orders add $12.00.

SSAR COMMITTEES FOR 1987-1988

Following the Veracruz meeting, President Norman Scott, Jr. appointed the following committee chairs and coordinators for the current year to report to the Board at the Ann Arbor meeting in 1988. Individuals with important matters pertaining to the activities of the Society committees should contact the relevant committee chair. Addresses for the committee chairs are included in the inside rear cover of each issue of *Herpetological Review*. A listing of committee members will appear in the March issue.

Conservation: Nat B. Fraser
Grants-in-Herpetology: Thomas H. Fritts
Kennedy Student Award: Eric Juterbock
Long-range Planning: James L. Christiansen
Meetings: Henry R. Mushinsky
Nominating: George Pisani
Regional Society Liaison: Stephen H. Hammack
Zoo Liaison: Donal Boyer
Common and Scientific Names Coordinator: Joseph T. Collins
Translations Coordinator: Robert D. Aldridge

●

SSAR ELECTIONS

Ballots were mailed without the return envelopes mentioned on the ballot. George Pisani, SSAR Elector, wishes it to be known that all original ballots sent in any sort of envelope were counted. ●

CAAR ACCOUNTS AVAILABLE

The **Catalogue of American Amphibians and Reptiles** is celebrating its 25th year of service to the herpetological community. The catalogue committee seeks to assign remaining open accounts for species native to the United States. The following lizard accounts are still available:

Callisaurus draconoides
Cnemidophorus burti
Cnemidophorus exsanguis
Cnemidophorus flagellicaudus
Cnemidophorus gularis
Cnemidophorus hyperythrus
Cnemidophorus inornatus
Cnemidophorus laredoensis
Cnemidophorus marmoratus
Cnemidophorus sexlineatus
Cnemidophorus sonorae
Cnemidophorus tigris
Crotaphytus collaris
Crotaphytus insularis
Eumeces fasciatus
Gerrhonotus liocephalus
Gerrhonotus panamintinus
Holbrookia maculata
Phrynosoma platyrhinos
Sceloporus clarki
Sceloporus cyanogenys
Sceloporus jarrovi
Sceloporus poinsetti
Sceloporus scalaris
Uta stansburiana
Xantusia riversiana

The **Catalogue** is also actively seeking persons interested in preparing accounts for species native to the remainder of the Western Hemisphere, as well as accounts for genera and families. Most such lizard accounts remain open. Persons interested in preparing any of the above-listed accounts, or seeking additional information, should contact the Sauria Editor, Dr. Andrew H. Price, Texas Natural Heritage Program, Texas Parks & Wildlife Department, 4200 Smith School Road, Austin, Texas 78744, USA ●

EXHIBITORS WANTED FOR 1988 JOINT HERPETOLOGY/ICHTHYOLOGY MEETING

The 1988 SSAR meeting will be held jointly, at the University of Michigan, with the Herpetologists' League, the Early Life History Section of the American Fisheries Society, the Elasmobranch Society, and the American Society of Ichthyologists and Herpetologists, on the occasion of the 75th anniversary of the founding of *Copeia*, the journal of the ASIH. The local committee for this meeting is in the process of contacting possible exhibitors. Any individual or organization is welcome to display herpetologically-oriented material (except live animals). The following information may be useful to potential exhibitors.

Registrants: Biologists, college professors, zoo and museum personnel, state and federal wildlife officials, graduate students in biology and serious lay persons with interests in amphibians and reptiles.

Previous exhibitors: Publishers, used-book companies, biological supply companies, manufacturers of animal collecting and housing equipment, artists (with animal themes), tee-shirt sellers, and travel services.

Cost: $100 for each table (ca. 4x6 feet). Artists who sell materials created by themselves will be charged $100 or $50 in donated arts or crafts; such persons are expected to be actively engaged in their work at the exhibit area. Other exhibitors may also donate $50 worth of goods in lieu of the table rental fee.

Exhibitors (or commercial organizations which will not have exhibits at the meeting) are also invited to place advertisements in the meeting program booklet. Full page, copy ready ads will cost $125; smaller ads will cost proportionately less.

For exhibit applications or further information, contact G. R. Smith, Museum of Zoology, University of Michigan, Ann Arbor, Michigan 48109, USA. (313) 764-0491. ●

DOCTORAL FELLOWSHIPS AT THE UNIVERSITY OF SOUTHWESTERN LOUISIANA

The Department of Biology at U.S.L. will offer three doctoral fellowships for students entering the doctoral program in August, 1988. One or more of these fellowships can be used to support students in the field of *herpetology*. Each fellowship has a life-span of three years (for students entering with a master's degree) or four years (for students with a bachelor's degree), and each carries a minimum stipend of $12,000 per year with waiver of tuition and fees. Also, each fellow will receive $500 per year for travel to scientific meetings and $2,000 per year for research expenses; supplemental research funds may be supplied by the Department of Biology, the Graduate Student Organization, and faculty grants. Because fellowships are duty-free, fellows can devote full time to course work and research. Current research in herpetology in this department emphasizes (but is not confined to) evolutionary morphology (Dr. James Jackson) and amphibian behavioral ecology (Dr. Robert Jaeger). For further information and application forms, write to Dr. Jackson or Dr. Jaeger at:

Department of Biology
The University of Southwestern Louisiana
Lafayette, LA 70504
or phone (318) 231-6748

NEWSNOTES

VOLUNTEER PROGRAM AT AMNH SOUTHWESTERN RESEARCH STATION

Approximately 20 volunteer positions are open in 1988 at the Southwestern Research Station of the American Museum of Natural History in Portal, Arizona. The volunteer program is run annually and offers students in the biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging at the Station are provided to volunteers in exchange for four hours per day of routine work chores, with the remaining time available for research activities.

Volunteers are needed between 10 March and 1 December and are appointed for part of this period, with a minimum appointment of six weeks. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Applicants for positions from March through May should submit forms by 15 February, summer volunteers, June through September, by 1 April. The program is open to both undergraduate and graduate students, who may pursue their own research projects.

For application forms, write: Resident Director, Southwestern Research Station of The American Museum of Natural History. Portal, Arizona 85632, USA. (602) 558-2396. ●

SUMMER COURSE ON AMPHIBIAN LARVAL BIOLOGY

An intensive, two-week summer course on "Amphibian Larval Biology" will be offered at the Highlands Biological Station in the Blue Ridge Mountains of southwestern North Carolina during the period 6-17 June 1988. Instructors will be Richard Wassersug (Dalhousie University), H. Bradley Shaffer (University of California, Davis), and James Hanken (University of Colorado). The course will include lectures, laboratories, field studies, and individual student projects. Among topics to be covered are study and identification of local larvae, morphology, ecology of amphibian larvae, evolution of complex life cycles and metamorphosis, and feeding behavior.

Credit for the course (three semester hours) will be available through either Western Carolina University or the University of North Carolina at Chapel Hill. The course may be taken without credit. For further information and application forms write: Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA. ●

THE FROGS OF BORACEIA, BRAZIL

Recordings of 34 of the 64 described species known from the Boracéia field station in the Atlantic Forests of southeastern Brazil are now available on cassette tape. The tape was made in conjunction with preparation of the forthcoming publication, *Frogs of Boracéia*. The recording will not be distributed with the publication and must be purchased separately.

The cost per cassette is $5 US, including postage and handling. Make check or money order out to: Smithsonian Institution and send order to:

Frogs of Boracéia Recording

Smithsonian Institution
Washington, D.C. 20560 USA ●

BOOKS AND JOURNALS SOUGHT FOR WILDLIFE MANAGEMENT PROGRAM IN COSTA RICA

The Environmental Sciences School of the National University of Costa Rica is setting up the first graduate wildlife management program in Latin America with assistance from World Wildlife Fund-US (WWF-US), United States Fish and Wildlife Service, International Affairs Office (USFWS) and the Organization of American States (OAS), among other organizations. The program, which is structured similar to a North American graduate program and leads to a Master's Degree in Wildlife Management, was initiated in February 1987 with 12 students from Central and South America.

Emphasis is broad based and focuses on endangered, non-game, cynegetic, and pest species, management of genetic resources and systems in tropical environments. Students work closely with human communities and government organizations during their three year training period.

A Wildlife Resource Documentation Center is planned to complement the Master's Degree Program. This is to serve not only the graduate students and staff at the University as a reference library but will also offer a much needed extension service to those biologists and administrators responsible for the research, management and conservation of wildlife resources in Latin America, especially in the region of Central America and the Caribbean.

Over the past two years the program has been able to accumulate a respectable collection of wildlife related materials that presently includes nearly 300 book titles, over 5,300 reprints, approximately 700 non-periodical documents, and incomplete collections of 17 scientific journals. In spite of these efforts, the center remains weak in the herpetological field. The coordinators of the program ask members of the Society for the Study of Amphibians and Reptiles for donations of books or back issues of journals to help correct this unfortunate situation. Donations should be sent in boxes weighing less than 40 pounds to Herb Raffaele, Office of International Affairs, U.S. Fish and Wildlife Service, Washington, D.C. 20240, USA. All donations will be formally acknowledged by the wildlife program.

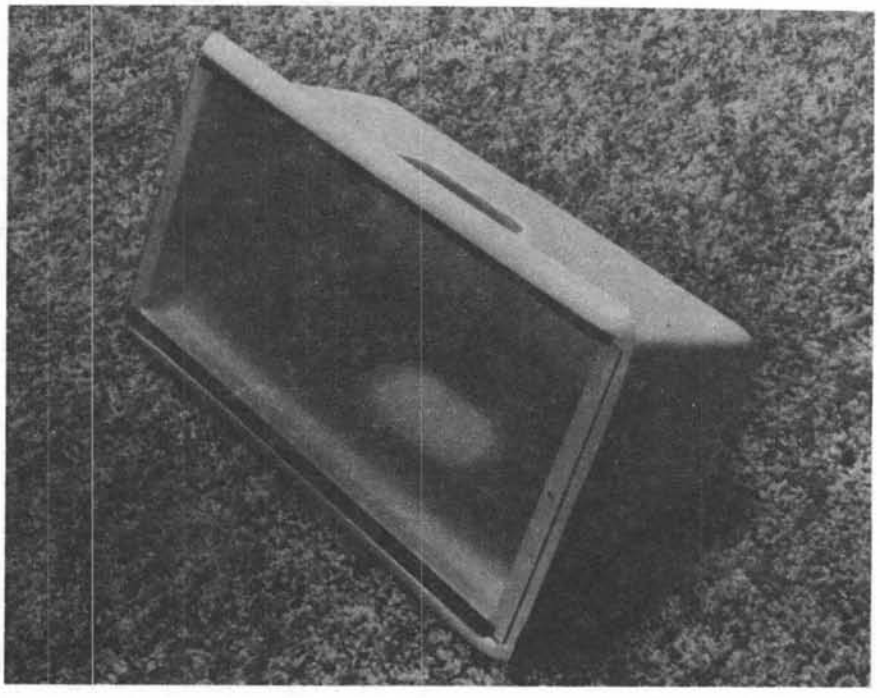
CLEMMYS GUTTATA RESEARCH

Our local unit of government in Northern Illinois is involved with research/management with the only known extant Illinois population of *Clemmys guttata*. We are seeking to communicate with individuals, groups, organizations or societies involved with research, management or conservation biology of this species.

. . .an excellent food source for most amphibians and reptiles.

With a dryweight analysis of 60% protein, 35% lipid and 5% carbohydrate, it is obvious why crickets are considered a valuable nutritional food source for amphibians and reptiles.

Fluker's Cricket Farm offers crickets in a variety of sizes and stages, from 1 day (1/8") to 6 weeks old (1") at a cost of $12/thousand (or a minimum order of 500 for $9.00) plus postage. Shipments are made year-round with guaranteed live delivery.



Fluker's Cricket Farm offers fine, healthy specimens. Our company takes pride in personal service, striving for individual attention and efficient shipping. We would appreciate an opportunity to serve you.

Phone (504) 343-7035.

Reptile Cages

FOR THE AMATEUR OR THE PROFESSIONAL

SUITABLE FOR SNAKES, LIZARDS, TARANTULAS, MANY SMALL PETS

- Durable ivory ABS plastic construction, unbreakable under normal usage.
- 3/16'' thick clear plastic sliding door for durability and unobstructed viewing.
- Sloping front for easy observation.
- No seams; all corners are rounded to facilitate ease in cleaning and provide freedom from mites.
- Odorless and stain resistant.
- Door and cage drilled on each end for padlock or pin for security. Doors and cages are template drilled for interchangability between cages. Door holes match cage holes no matter how plastic door inserted.
- Top venting can be used for lighting or temperature control. Cage easily heated by resting on heat pad or using stick-on type aquarium heaters.
- Flat back allows standing cage upright for reptile privacy if desired.
- Tapered form allows stacking one inside another to reduce storage area.

24'' Reptile Cage $33.95

24'' Wide, 12¼'' High, 12½'' Deep
Approx. 250 sq. in. floor area
Single Vent

36'' Reptile Cage $58.95

36'' Wide, 18'' High, 19'' Deep
Approx. 580 sq. in. floor area
Double Vent

Prices **include** freight charges and are shipped via UPS. Please send check or money order. Kansas Residents add 3% sales tax. COD shipments made adding shipping and COD charges, $10.00 deposit required with order.

Institutions, zoos, and pet dealers are invited to write on letterhead for quantity prices.

MEETINGS

BRITISH HERPETOLOGICAL SOCIETY LONDON MEETINGS 1988

Meetings are held in the Lecture Theatre of the Linnean Society of London, Burlington House, Piccadilly, London W1, and start at 7:00 pm, ending at 9:00 pm, unless indicated otherwise. For further details and membership, please write to BHS, c/o Zoological Society of London, Regent's Park, London NW1 4RY, U.K. As always, SSAR members and other North American-based herpetologists visiting or passing through London are most welcome.

March 3 - Jonathan Wright: Population Ecology of Two Mediterranean Tortoises in Northern Greece - Account of a Joint Universities Expedition, 1985.

March 29 - A.G.M. (see separate Agenda), followed by Peter Curry: A Case for Captivity.

April 27 - Dr David J. Bullock: Herpetofauna of The Northern Mauritian Islands (Indian Ocean).

May 26 - David Risley: Captive Breeding of Reptiles in The London Zoo.

July 6 - *Amphibia and Reptilia Worldwide: Their Care and Breeding.* A discussion organized by the Captive Breeding Committee (Chairman: Mike Linley). Members are encouraged to bring live animals, preserved specimens, amphibian voice recordings and 35 mm colour slides for display and to illustrate discussions.

September - *Care and Breeding of Amphibians and Reptiles: An Open Meeting.* Contributions from members - live animals, slides, etc. There will be facilities for the sale and exchange of members' private home-bred stock. Saturday date and venue to be arranged.

October 13 - Talk to be arranged, hopefully Paul Edgar, on the herpetofauna of Indonesia.

November 30 - Mike Linley will show some herpetological films not previously screened by Anglia TV. Date to be confirmed.

Please note that *the Herpetological Journal*, the Society's newly-named scientific publication, now publishes mini-reviews, short notes with a single data set, and from December 1987 short articles on contentious or generally controversial matters in herpetology. Mini-reviews are normally solicited by the Editor (Dr T.J.C. Beebee, School of Biology, University of Sussex, Falmer, Brighton BN1 9QG, U.K.). ●

SYRACUSE CONFERENCE TO ADDRESS ECOSYSTEM MANAGEMENT

The State University of New York College of Environmental Science and Forestry (ESF) will host a conference on ecosystem management titled "Rare Species and Significant Habitats" on 6-9 June 1988.

The conference will be held in conjunction with the 15th Annual Natural Areas Conference and the 10th Annual Meeting of the Natural Areas Association. Co-sponsors of the conference include the Natural Areas Association, the New York State Museum, the New York State Department of Environmental Conservation Divisions of Fish and Wildlife and Lands and Forests, the New York State Office of Parks, Recreation and Historic Preservation, and The Nature Conservancy of New York.

The conference aims to promote sensitive management of rare species and significant habitats through a forum allowing botanists, zoologists, ecologists and natural resource managers to share their research findings, experiences and viewpoints. The conference will provide a unique opportunity for interaction between scientists and managers through papers, poster sessions, field trips and workshops.

For more information on the conference, contact Dr. Donald J. Leopold, 333 Illick Hall, State University of New York College of Environmental Science and Forestry, Syracuse, New York 13210, USA. ●

CALL FOR PAPERS

The 12th Annual International Herpetological Symposium on Captive Propagation and Husbandry will take place on 15-18 June 1988 in the New York-New Jersey Metropolitan

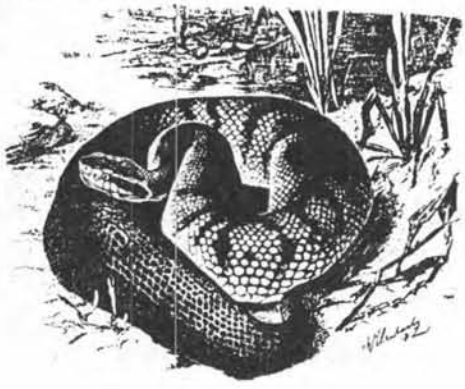
AUSTRALIAN SOCIETY OF HERPETOLOGISTS ANNUAL MEETING 1987

The Australian Society of Herpetologists held its 17th annual meeting on February 13 to 15, 1987, at Edrom Lodge near Eden, New South Wales. The venue was idyllic - an old mansion set in delightful gardens and bushland, 100 metres from a superb beach on Twofold Bay. The warm weather encouraged aquatic activities by the conference participants between formal sessions, and there were probably as many herpetological conversations in the blue Pacific as in the seminar rooms.

Twenty-four papers were presented at the meeting, and about 50 people attended. There was a far greater concentration on ecology (rather than taxonomy, morphology or physiology) and on reptiles (rather than frogs) than has been evident at most previous meetings. David Slip (University of Sydney) won the major student prize for his presentation on ecology of diamond pythons; other student awards went to America Cuff (Macquarie University) for work on environmental sex determination in crocodiles, and to Darryl Houston (University of Sydney) for ecological studies on acrochordid snakes.

The business meeting considered several issues. The society's policy statement on conservation was formally ratified, and new office-bearers elected (President - Dick Barwick; Vice-president - John Coventry; Secretary-treasurer - John Wombey; Public Officer - Ric Longmore; Councilor - Rick Shine). The next A.S.H. meeting has been tentatively scheduled for the third week of August 1988, at the Queensland Museum in Brisbane. Overseas herpetologists are welcome to attend.



A full list of authors and titles at the 1987 meeting is given below:

Stephen Morton and *Craig James:* "Diversity of Australia's arid zone lizards: A reappraisal."
Richard Shine: "Ecological causes for sexual dimorphism in snakes."
David Slip: "Ecology of diamond pythons: a brief overview."
Rodney Kennett and Arthur Georges: "Growth and reproduction of *Chelodina longicollis.*"
Darryl Houston: "Where have all my filesnakes gone?"
David Slip, Richard Shine and Richard Braithwaite: "A radiotelemetric and population ecology study of water pythons, *Liasis fuscus.*"
David Carter: "Ecology of the Lace Monitor: Pre-PhD ideas."
Murray Littlejohn and G. Watson: "*Litoria ewingi* in New Zealand: A preliminary analysis of the structure of advertisement calls."
David Choquenot and Allen Greer: "Intrapopulational and interspecific variation in limb and presacral vertebrae configuration in the genus *Hemiergis.*"
Glen Shea: "Ontogenetic changes and species differences in the dentition of Bluetongue lizards (*Tiliqua*)."
Richard Shine and *Robert Lambeck:* "Why does the frillneck lizard have a frill?"
Terry Annable: "Sloughing behaviour of *Underwoodisaurus milii* in captivity."
Harry Ehmann: "Post-oviposition egg care by skinks."
Gregory Mengden: "Phylogeny of pythons."
Elizabeth Yeatman: "Ecology of *Tiliqua.*"
John Gee: "Subsurface buoyancy control by the sea snake *Pelamis platurus.*"
Harold Heatwole and William Dunson: "Blood and plasma volumes and hematocrits of some marine snakes."
Arthur Georges: "Nesting ecology of the pig-nosed turtle *Carettochelys insculpta.*"
Michael Thompson. "Nesting ecology and egg physiology of Tuatara, *Sphenodon punctatus,* on Stephens Island, New Zealand."
Linda Schwarzkopf and R. Brooks: "Nest site selection and offspring sex ratio in painted turtles (*Chrysemys picta*)."
America Cuff: "Environmental sex determination of the saltwater crocodile *(Crocodylus porosus).*"
Richard Longmore: "Atlas of Elapid snakes of Australia. A concept - a product."
Garry Webb: "The impact of various logging treatments on lizards of a montane eucalypt forest."
Daniel Lunney, Peggy Eby and Michael O'Connell: "Changes in reptile populations in Mumbulla State Forest, near Bega, NSW, following logging, fire and drought."

University of Sydney ●

ANNUAL ASC MEETING

The Association of Systematics Collections (ASC) will hold its Annual Meeting at the Field Museum, Chicago, Illinois, 11-13 May 1988. An all-day workshop on *Living Collections,* on 13 May, will include representatives from museums, zoos, aquaria, gardens, culture collections, NSF, and NIH. On 12 May there will be a workshop on *Endangered Collections.* For further information contact: The Association of Systematics Collections, 730 11th Street NW, 2nd Floor, Washington, D.C. 20001. (202) 347-2850. ●

FEATURES

THE SIN OF ANECDOTAL WRITING

An anecdote is defined as a short account of an interesting or humorous incident. The word is derived from Greek, *anekdota,* "things unpublished." Nevertheless, published writings about animals have often consisted of anecdotes. Increasing pressures on modern-day authors, reviewers and editors to avoid unnecessarily lengthy, rambling or unfocused accounts, and to achieve maximum economy in publishing results of research have caused anecdotal writing to fall into ill repute. A statement by a reviewer that a manuscript offered for publication is anecdotal has become a severe condemnation. It makes no difference (to some reviewers, at least) whether the "anecdote" is a humorous account relating how the author missed sleep on his last field trip, or instead describes previously unobserved aspects of a species' life history. Any sort of narrative is equated with an anecdote, and a single sentence mentioning time and place of a specific incident can be cause for the entire paper to be branded as anecdotal, with the implication that it is, therefore, unsuited for publication.

Admittedly, there are anecdotes that add nothing to the scientific merit of a paper; some may inject a touch of humor, and some may only amount to "padding." Nevertheless, I contend that narrative accounts of rarely observed events in species' life histories sometimes have much merit and value. On the University of Kansas Natural History Reservation where 37 species of amphibians and reptiles are known to occur, I have spent 37 consecutive years of field work, yet I have observed the complete sequence of courtship and copulation in only 14% of the resident species. Likewise, I have observed the sequence of stalking, capture and eating of prey in just 14% of the species, not all the same as those of the first group. I cite these figures to make the point that even routine occurrences in the lives of amphibians and reptiles easily escape attention because of secretive habits. When an observer is fortunate enough to see and record behavior significant in the natural history of a species, his observations should be published. The advocates of biometrical methods need to recognize that some types of behavior are not readily quantified because they are so rarely observed. Even a single observation may constitute a valuable contribution, and may be a break-through in understanding the species' ecology. There are many kinds of anecdotes, and the fact that some are trivial is a poor excuse for condemning all narrative statements or accounts in scientific writing.

HERPETOLOGICAL HUSBANDRY

See Herp. Review 18(1) for author's instructions.

FEEDING BEHAVIOR OF A FALSE CORAL SNAKE, *Pseudoboa neuwiedii*

An adult female *Pseudoboa neuwiedii* was collected near Cartagene, Colombia on 28 December 1985. The snake has been maintained in a 30 l aquarium in about 15 cm of soil in the museum facilities in Madrid, Spain since 6 January 1986. Room temperature ranged from 16-30° C; water and refuge have always been available.

During the first three weeks of captivity the snake refused a variety of prey such as frogs, lizards, eggs, earthworms and insects. It was finally force-fed with fresh beef.

The snake began feeding voluntarily on live *Blanus cinereus* on 8 March 1986. The next ingestions of *Blanus cinereus* occurred on 12 and 24 April, 4 and 18 May, 9 and 20 June, and 3 July.

The behavior of the snake was always the same: As soon as it recognized the *Blanus* it quickly struck it in the middle of the body and did not release its hold despite the vigorous efforts of the victim to escape. In some instances the snake was firmly held by the jaws of the *Blanus*. After ca. 15 min. the *Blanus* would cease to struggle. Swallowing was completed in an additional five min, with the head being ingested first.

TECHNIQUES

PHOTOGRAPHS AND DENTAL CASTS AS PERMANENT RECORDS FOR AGE ESTIMATES AND GROWTH STUDIES OF TURTLES

Permanent physical records of the surface details of turtle scutes can provide a variety of information unavailable through either field observations or by killing individuals to obtain long bones or the carapace. Several forms of permanent records of the topography of carapacial or plastral scutes, including photographs (Moll and Legler 1971, Dobie 1971), photocopies (J. W. Gibbons, pers. comm.), and graphite rubbings (Moll and Legler 1971), have been used for age estimation or individual identification.

Physical records have a distinct advantage over field measurements, as repeated measurements are easily made in the laboratory, and new measurements are possible any time after the records have been made. In addition, direct comparison of scute surface details from the same individual in different years is possible with detailed records. Two types of physical records facilitate estimates of age and growth in turtles. Black and white photographs may be taken of the surface of the fourth vertebral scutes of adult and juvenile turtles and dental casts of the fourth vertebral scutes can be made. Below we describe both techniques, and evaluate the records in terms of detail, distortion, and cost.

PHOTOGRAPHIC TECHNIQUE

The objective of photographing surface details on carapacial scutes was to provide permanent records of the growth lines of individuals. A scale was included in each photograph, so that measurements could be made from finished prints. Fine-grain film (Ilford FP11 or Kodak Plus-X-Pan black and white print film) allowed enlargement for measurement and counting. The distance (45 cm) and angle (90°) from lens to turtle were standardized. Prior to field photography, several test exposures were made and developed immediately. A 35 mm SLR camera with macro-lens was positioned to fill the viewfinder with the fourth vertebral scute, and an adjacent ruler. The flash was positioned to throw highlights off otherwise dark relief features. A slight overexposure (for neutral gray) was required to capture details of surface relief on the dark carapace. The exposures were bracketed a full stop either side of the exposure that gave good results in the laboratory.

Turtles were restrained (Galbraith and Brooks 1983), and the region of the turtle's carapace to be photographed was cleaned of algae and dirt by gentle scrubbing with mild detergents using a plastic sponge or brush.

DENTAL CAST TECHNIQUE

The objective in making casts was to provide fine-resolution permanent records of details on portions of the turtles' carapaces, independent of the photographs. The prime requisites were speed, inexpensive materials, safety for the animals, and lack of distortion.

Casts required making a negative mold directly from the object being modelled (Fig. 1), and then casting the finished positive from the mold (Fig. 2). Very finely resolved molds have been made for paleontological purposes using latex rubber, but these are expensive and require many hours for the mold to set and cure (Baird 1955). The most common material for dental casts is alginate, an inexpensive, non-toxic powder that gels quickly after being wetted (Coe Alginate, Coe Laboratories, Inc. 3737 West 127th Street, Chicago, Illinois 60658 USA).

To make a cast, the turtle was restrained and the fourth vertebral scute was cleaned as for the photographs. All detergent was thoroughly rinsed away to avoid contaminating the alginate. The soft, gelatinous alginate required support during setting and after gelation to avoid distortion. 'Mother molds,' perforated plastic plates or as rough molds made previously out of dental stone (Vel Mix Stone, Sybron/Kerr Products, 28200 Wick Road, Romulus, Michigan 48174 USA) effectively supported the alginate (Fig. 1). The surface of the carapace to be modeled was wetted before molding. Setting time of the mold generally required less than five minutes.

Once the alginate mold had set, it was removed from the carapace and rinsed with clean water. The finished positive was then made using the liquid dental stone (Fig. 2).

EVALUATION OF THE TECHNIQUES

To assess agreement between measurements made in the field and on photographs and casts, the length of the fourth vertebral scute was measured by hand-held caliper in the field on 46 adult and juvenile snapping turtles in 1984. The same measurement was repeated blindly from photographs and from casts from the same individuals later in the laboratory. On average, the difference between field measurements and photographs

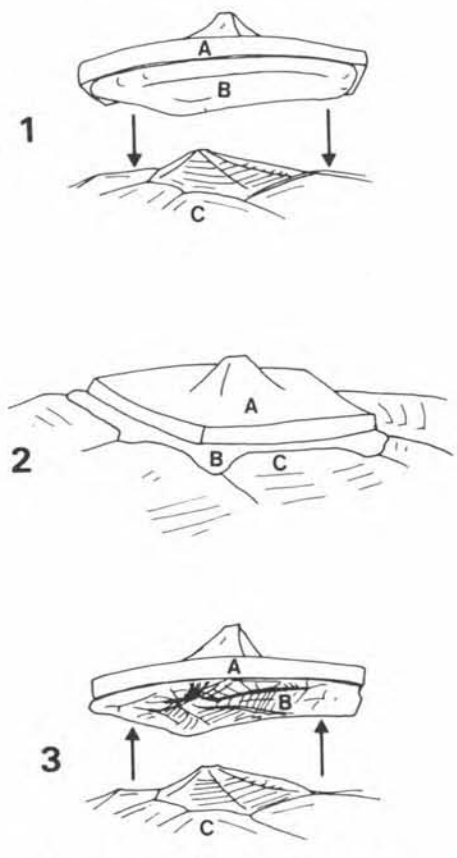

Figure 1. Steps in making the negative mold for casts of scutes. 1. The mother-mold (A), supporting the alginate paste (B) is lowered onto the carapace (C), quickly, with a rolling motion. 2. The mother-mold is pressed down until alginate is forced out from underneath. 3. After setting (3-5 min.), the completed mold is lifted from the carapace with a quick twist.

Amphibians and Reptiles in West Virginia

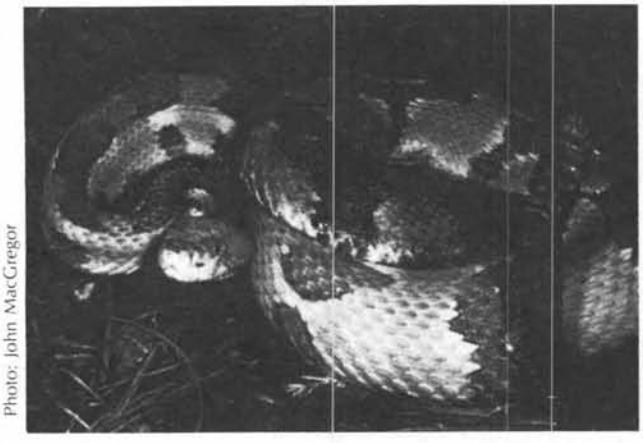

Photo: John MacGregor

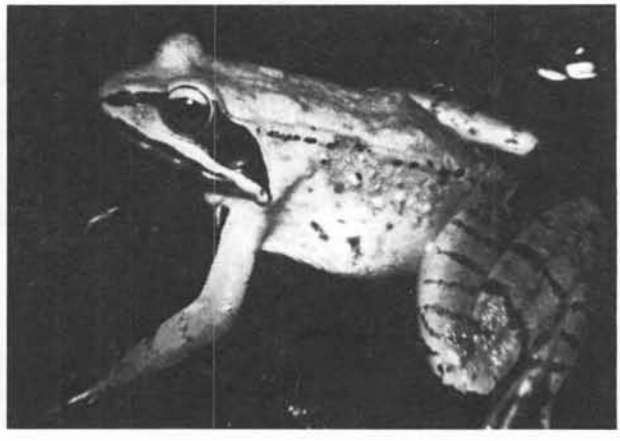

Photo: Robert Birch

N. Bayard Green and Thomas K. Pauley

"The first comprehensive scientific report on the amphibians and reptiles of West Virginia . . . a valuable contribution to the field of herpetology."—Robert H. Mount, Auburn University

"It is a major contribution to our knowledge of these creatures, a contribution made more important by West Virginia's location in a critical herpetological area of the eastern United States."—Joseph T. Collins, University of Kansas Museum of Natural History

In a handy, guidebook format, *Amphibians and Reptiles in West Virginia* collects the available information on the distribution, habitat, and seasonal activities of the eighty-five species of amphibians and reptiles which have been collected in West Virginia.

Each species account includes:

- West Virginia range map
- color photograph
- complete species description: coloration, pattern, size, comparisons with similar species
- discussion of habits and habitat, breeding behavior

Amphibians and Reptiles in West Virginia also features:

- brief history of herpetology in West Virginia
- overview of the state's physiography and climate
- taxonomic keys
- complete bibliography

N. Bayard Green, Professor Emeritus of Zoology at Marshall University, was until 1971 Curator of the Herpetological Collections of the West Virginia Biological Survey. Thomas K. Pauley is Associate Professor of Biology at Marshall University.

was 0.70±0.50 % (mean±1 SE). The difference between field measurements and measurements made on casts was 0.30±0.30 %.

Distortion within individual photographs was assessed by comparison of two scales incorporated in the photographs, at right angles to each other. The scale parallel to the vertebral column of the turtle was on average shortened relative to the scale at right angles to it (Mean distortion = -1.04±0.16%, n = 86, t = -6.37, $P < 0.01$.). This distortion may have been the result of a consistent error in the angle at which the camera was held relative to the turtle.

The cast-making process was assessed separately in a laboratory trial. Ten casts were made from the same object, a smooth plastic disk approximately 6.5 cm in diameter and 1 cm thick. Cemented to the surface of the large plastic disk were three smaller metal disks, ranging in diameter from ca. 1.8 cm to 2.1 cm, each less than 2 mm in thickness. The casts were made over a period of two months and each was allowed to dry thoroughly (at least a week) prior to measurement.

Eight measurements were made on each cast: two diameters at right angles were measured for the plastic disk and each of the metal disks. A paired t-test was used to test

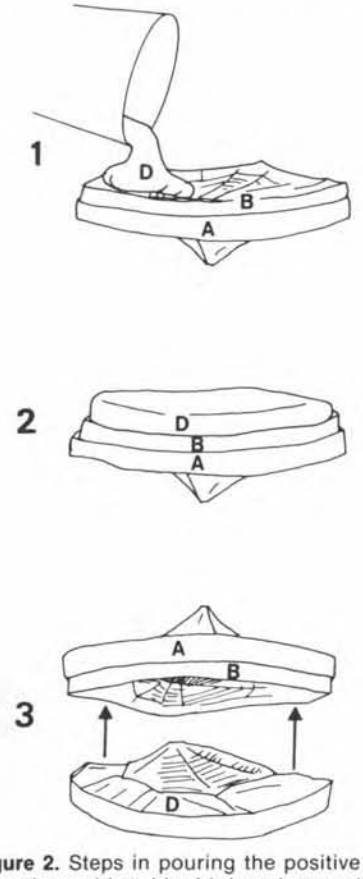

Figure 2. Steps in pouring the positive cast from the mold. 1. Liquid dental stone (D) is poured into the alginate mold from the side, to lessen air-bubble entrapment. The mold is tapped against the tabletop to encourage air bubbles to rise. 2. The poured casting is set aside for at least four hours. 3. The finished cast (D) is removed from the mold with a quick pull. The alginate mold is discarded, and the mother-mold is cleaned for re-use.
